Yahoo Group Archive: loopantennas (2013 — 2017)

Yahoo Group summary: This is the Loop Antenna Group to Ask Your Questions, Get Answers and Information about Loop Antennas for improved your Radio Listening and Enjoyment. \n \n This is your "HOW TO" Loop Antenna Forum to : Get Information, Plan, Design and Build Loop Antennas for both Radio Reception and Transmission. Air loops, magnetic loops, ferrite loops, shielded, unshielded, SLF to any frequency you can make a loop antenna for.\n \n Loop antennas are used to reduce interference or can be used as compact antennas or for radio direction finding (RDF).\n \n Post Your Question Here! To Get Needed Information and Opinions about a Commercial "Ready-Made" Loop Antenna or help with a home-made loop.\n \n Discussion of this Group is focused on the subject of Loop Antennas. All types of Loop Antennas including Ferrite Rod Loop Antennas; Air-Core Loop Antennas, Shielded Coax Cable Loop Antennas; all types of loop antennas.\n \n Loop Antennas for All Bands : SLF, VLF, LF, MF, HF, VHF, UHF, SHF etc. Longwave, Me

Active AM Antenna With Twin Coil Ferrite by C. Crane Co.
http://www.ccrane.com/antennas/am-antennas/

JLKolb?s antenna links including the KRS AA-1 Active Antenna schematic, antenna preamplfiers, center-tapped loops, and a dual gate FET preselector.
http://jlkolb.cts.com/site/ant.htm

Directional Terminated MW/LW Loop by WellBroook (UK)
K9AY is the Remote Controlled Variable Termination; Provides a Cardioid Reception Pattern with up to 30dB Gain Front-to-Back; Uses Two Delta Loops.
http://www.wellbrook.uk.com/K9AY.html

Kiwa - High Performance MW Air-Core Loop Antenna
High Performance MW Air-Core Loop Antenna by KIWA
http://www.kiwa.com/kiwaloop.html

Palomar Engineers Loop Antennas LW-MW-SW2
Palomar's Loop Antenna gives superb performance on the AM medium-wave broadcast band. The loop rotates and tilts to give deep nulls so you can eliminate local interference. It also allows you to null out a station and listen to another one on the same frequency.
http://www.palomar-engineers.com/Loop_Antenna/loop_antenna.html

The Quantum loop antennas, now V2.0
http://www.dxtools.com/

Terk AM loop at Amazon.com
Here is a place you can buy yourself a TERK AM loop antenna, even some other stuff that is kind of off topic to talk about. 73
http://www.amazon.com/exec/obidos/ASIN/B000069EUW/qid=1075080062/sr=2-1/ref=sr_2_1/102-8712984-4397719

WL1030 by the late Maartenhagg. Plans placed on this website by his friends in his honor.
http://wl1030.com/content/

C Crane Company
They sell the Justice AM Loop Antenna, Select A Tenna, Terk AM 1000
http://www.ccrane.com

Kiwa Electronics
Kwia makes the best products for you and your radio equipment, and also improves things that needed improvement a long time ago.
http://www.kiwa.com

Stormwise Ferrite Rods
Get some huge ferrite rods and a converter to go along with its, heck it even comes with project book.
http://www.stormwise.com

Universal Radio Company
They sell all sorts of loops big and small for LW/MW/SW and VLF also 10 kHz to 15 MHz
http://www.rffun.com

ALA-1530
Find the best UK LF/MF antenna here.
http://www.wellbrook.uk.com/

AOR
This is the site that sells the AOR loop
http://www.aorja.com/ant-e.html

Kiwa Electronics
The maker of the air core loop antenna and other useful items that you may want on your wish list.
http://www.kiwa.com

LF Engineering Company
A group of engineers, who make products for VLF/LF listening even ELF loops!
http://www.lfengineering.com

Select A Tenna by Intensitronics Corp
The maker of the select A tenna, a great AM loop antenna that is a little bigger than the terk
discontinued

Terk Technolegies
The maker of the best sold AM and I use also called the AM-1000 AM loop antenna, there is also technical information on how it works.
http://www.terk.com

Torus Tuner Loop Company
A very specially made loop that is almost as big as a hula hoop
discontinued

GRAHN (Germany) Specialized Loop Antennas for MW and SW Reception Contributed by radiohighfreq
Grahn offers both Ferrite Rod Antennas and Shielded Loop Antennas. Translated from the Gremany Language Webpages here is the "Grahn Specialized Loop Antennas for MW and SW Reception" ULR Address: http://www.grahn-spezialantennen.de/
Use the Google Translate a web Page Tool http://www.google.com/language_tools to convert these webpages to English.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

9527. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-01-01 16:54:05 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 9527

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

9528. For Sale 8" MW Band FSL antenna

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-01-04 14:27:48 UTC
From: everettsharp@aol.com
Topic: 9528 Message: 9528
Attachments: 3 described; binary payloads are missing from this source WARC

If anyone is interest in a MW Band 8" FSL, as described below, which I am asking $300 + shipping for, Then please contacted off list at _everettsharp@..._ (mailto:everettsharp@...)

The 8" FSL is 5" wide and 8" in diameter, only weights 7 pounds, 17" tall, including the carry handle and is mounted on a Lazy Susan. It has 32 Russian 125 X 16 X 4 mm ferrite bars, which are no longer available, that are epoxied to the plastic pipe and they are covered with fiberglass cloth, which was also covered with 2 coats of epoxy. The outside diameter of the FSL with the ferrite on it is 7". The ferrite is covered with 1/2 thick PE foam, thus with a ending diameter of 8".

The coil is 18 turns of 660/46 Litz wire, there is also a 1 turn winding next to the main winding that is used for a coupling coil, which is connected to a matching transformer, this is for a 50 ohm output that can connected to a desk top radio, which has a BNC connector on the back side. It also works very well using induction coupling for portable radios and brings them to life. The tuning capacitor, is a N 50 (10 to 365 pf), with has a 8:1 tuning ratio. The tuning range/coverage is 2060-530 KHz.

The FSL, is a one of a kind and is constructed very well. It has very sharp tuning and very good rotational nulls. Also based on my evaluation, it's performed is better than a 3' box loop. However, it shows lower S meter readings than the box loop, but a much better S/N than the air loop. It's appearance is in no way perfect, as it is home made, but it is probably one of the best construed and looking FSL's that has been built to date. I have several articles that are posted on the ULR-DX site covering many of my FSL antennas projects and experiments. and several have been posted on this site.

Below are some pictures of it:

So if anyone is interested, please let me know. The estimated, State Side, shipping cost is $25. So the total cost would be $325 delivered. I can take either a money order, or PayPal payment.

Everett N8CNP

9529. Radio Milne Bay on a KAZ 3/12m

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-01-04 19:54:48 UTC
From: KGB
Topic: 9529 Message: 9529

Hi everybody,

A little OT but here we go: I think I have Radio Milne Bay on 3365kHz in my headphones tonight. I have watched the PNG frequencies every evening since August. Often there is a carrier but seldom any modulation. Tonight it is rather good reception. The music is OK but the speec is very muddy. Just wanted ask the group
1 if anyone has heard R Minle Bay and can confirm the muddy modulation
2 if anyone knows of a good audio filter/equalizer to further process the received audio.

My setup is Perseus + Studio 1. Antenna is a 3/12m KAZ with Wellbrook FLG100LN (great amp).

I also have a 5/20m KAZ for NA MW DX. First I made it 6/24m but that was to much together with the FLG100LN, Perseus had frequent ADC clip. The last is sentence to get a more loopantenna touch to the message :-).

73,
Kjell-Göra SM4GRP

From: Rick Karlquist
Topic: 9528 Message: 9532

Can someone on the list educate us about the value proposition
for building something like this? For example, compared to the
single ferrite rod in my Superradio, what does this do better?
Perhaps more signal? Or does it have sharper nulls? Wider
or narrower bandwidth? Another thing I don't understand is
that it looks like the resulting ensemble is rather short and
fat. Why wouldn't you build it longer and skinnier?

How does it compare to, for example, a 10 foot diameter wire loop?

Is this just an example of "throwing ferrite at the problem?"

Just trying to learn something here.

Hi Dean,

Some of the experimenters have tried the EMI ferrite bars that were offered on eBay, but they found that they were trash. Your other option is to use some of the mix 61 3/8 X 7.5" ferrite rods, but @ $15 each and requiring about 54 of them, it would cost you over $800 in ferrite to duplicate what I am offer for sale.

There are still some of the Russian 62 X 12 X 4 mm bars for sale on eBay, at 20 for $13 delivered, it would take 86 bars at a cost of $56. I have over a 1000 of them and they work very well and I have used them in many experiments making FSL's as wide as 12" with the bars butter together. Also there are now some Chines bars that are being offered on eBay that are 55 X 13 X 5 mm, 5 of then at a cost of $5 delivered, it would take 80 of them at a cost of $80. I have never tried them and have no idea if they would even work.

Then there is one last option and that is to build a Stacked Toroid Loop Stick, using FT140-61 toroids. You can buy 30 of them from Kit Parts for $70 delivered. This will make you a 15" X 1.4" ferrite rod that works very well, but not as good as a 8" FSL. There should be a article posted on this site that I wrote that gives a lot of very good information that would help you if you decide to go that direction. I was able to make dual band configurations with the STLS that would either cover the MW and LW bands, or MW and a portion of the tropical bands and MW.

Other cost considerations are the N-50, with 8:1 ratio, at about $25 and the 660/46 Litz wire at about $.030 per foot. With the Litz wire you will have to order more then what you will use and you will end up dump about 30 to 40% of it into the trash can. It takes a lot of trial and error and a lot of man hours to get one to work. I sure would not make one for $300 and the only reason I am selling it is that I am trying to down size my antenna collection. The money will only be use to fund other antenna experiments.

I don't see the pics Everett.

BTW if anyone has a source for some ferrite bars i would be interested,i'm not too keen on getting them from the Ukrain etc.

Thanks Dean_0

Rick,

AlI I can tell you is that it's performance is about equal to a 4' box loop. You will see lower S meter readings with the FSL, but the FSL has much lower noise and the week signals are easer to hear. There have been many articles written about the FSL antenna and many of them are posted on the URL DX yahoo site. I have done a lot of experimenting with different FSL configurations and some of the articles that I have written are posted on this site.

Can someone on the list educate us about the value proposition for building something like this? For example, compared to the single ferrite rod in my Superradio, what does this do better? Perhaps more signal? Or does it have sharper nulls? Wider or narrower bandwidth? Another thing I don't understand is that it looks like the resulting ensemble is rather short and fat. Why wouldn't you build it longer and skinnier?

How does it compare to, for example, a 10 foot diameter wire loop?

Is this just an example of "throwing ferrite at the problem?"

Just trying to learn something here.

Everett:

I would say that's a good price for a working FSL of that size. Just my $0.02 on that.

One "trick" I've leaned for saving on Litz waste is to use stranded/insulated hookup wire with close to the same diameter and find the number of turns for the upper end of the desired band then wind with the Litz, the distributed capacitance for the Litz will be a bit higher so trimming a turn or two on a close wound ferrite after assembly saves me a lot of $ compared to trial and error. With air core loops the difference in distributed capacitance is negligible if there's 1/4" or more spacing between turns.

Tim,

Thanks for the tip. If you have looked at any of my articles you will notice a lot of spliced Litz wire in the pictures. To date
I have made up and wound well over a 100 different coil/FSL configurations.

The stacked toroidal loop stick project that I experimented with worked out extremely well and I was quite pleased with how well it worked. I just ordered 60 more of the FT140-61 toroids from kit parts. I plan on making a 23" long loop stick with 4 to 6 coils in parallel, as I have seen some advantages in multi coils in parallel.

It has 32 Russian 125 X 16 X 4 mm ferrite bars, which are no longer available, that are epoxied to the plastic pipe and they are covered with fiberglass cloth, which was also covered with 2 coats of epoxy. The outside diameter of the FSL with the ferrite on it is 7". The ferrite is covered with 1/2 thick PE foam, thus with a ending diameter of 8".
>
> The coil is 18 turns of 660/46 Litz wire, there is also a 1 turn winding next to the main winding that is used for a coupling coil, which is connected to a matching transformer, this is for a 50 ohm output that can connected to a desk top radio, which has a BNC connector on the back side. It also works very well using induction coupling for portable radios and brings them to life. The tuning capacitor, is a N 50 (10 to 365 pf), with has a 8:1 tuning ratio. The tuning range/coverage is 2060-530 KHz.
>
> The FSL, is a one of a kind and is constructed very well. It has very sharp tuning and very good rotational nulls. Also based on my evaluation, it's performed is better than a 3' box loop. However, it shows lower S meter readings than the box loop, but a much better S/N than the air loop. It's appearance is in no way perfect, as it is home made, but it is probably one of the best construed and looking FSL's that has been built to date. I have several articles that are posted on the ULR-DX site covering many of my FSL antennas projects and experiments. and several have been posted on this site.

Hi Dean,

Yes I have seen that article, that is what got all of the experimenters fired up and the low cost Russian ferrite. However when building a larger FSL you will run into some distributed capacitance issues with standard wire, which is a Q killer, thus reducing the tuning sharpness and band coverage. That is why almost of all of the FSL's are built using Litz wire.

I question some of the theory sited in that article, but it was what got us all started with experimenting with FSL's.

Okay, I'll bite. What does Litz wire have to do with
distributed capacitance?

9544. Value proposistion for FSLs (Rick question)

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-01-05 19:49:33 UTC
From: lowalacrity
Topic: 9528 Message: 9544

Rick,
More to your actual question, In my experience, I haven't found that much performance improvement when using add-on loops to already high performing radios such as yours. They already have relatively large ferrite loops built in. With a cheap transistor radio, they make a huge difference. Same with the new generation of Ultra Lights, they have small ferrite rods that benefit from augmentation. The DSP technology they employ makes them unbeatable.
To the fat vs. skinny question. The resurgence and popularity of FSL's attest to the superiority of loop diameter. Like air core loops, I think it has to do with aperture. The thing with large air cores is that they become cumbersome. Ferrite core loops, especially FSL's, condense that performance down. The litz wire helps a great deal to, with the added "Q". With sensitivity comes added noise. Contra (counter wound) windings come into play here. They do make a difference. My work with Everett's Stacked Toroid Ferrite Loop has shown me this and made it my reference loop of choice. (plug)..
I hope this helps.
73,
John KG6ZBN

OH! how i have struggled to understand (visualize) what he is saying in the article! ,after reading it ,well trying to read it a hundred times i just decided to build one some day and compare it to the 4 foot loop i built ,it was a decent performer , but as you might guess not useful in my shack.

Anyway you guy's should at some point right an article on your findings,one thing i'd really like to try is take the RF 2200 out into the wasteland with an FSL :)

Thanks
Dean_0

9546. Is this preamp worth anything ?

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-01-05 22:28:22 UTC
From: Alberto I2PHD
Topic: 9546 Message: 9546

Hi all,

this is the group where all the loop gurus lurk, so I think this is the best place where to ask suggestions
about this simple schematic of a preamplifier I have just built for my single turn loop, made of 3/8" copper
tube, about 1.3 meter (4.8 feet) in diameter, which in my intentions should cover from 60 kHz to the
21 MHz ham band.

I simulated it with PSpice, and it looks like it works. The problem being that it is not quite bullet proof as
far as intermodulation is concerned... especially in the evening, with the field strength that AM broadcast
stations have here in Europe, some intermodulation raises its ugly head...

I know that persons very expert in this field read this group (e.g. Jack K8ZOA and Chris Trask N7ZWY),
so I am asking advice. I do not pretend that you reveal how you built your commercial preamps,
that work very well, just if you have suggestions about changes to do to this schematic, even if they
are of the type : "Throw it away, it is good for nothing" :-)

This preamp tries to have a very low input impedance, to match that of the loop, and to avoid the need
to electrically shield the loop itself, as it, electrically speaking, is almost at ground potential.

Thanks for any help.

This is the schematic :

A few comments - I have not tried to analyze your circuit in detail so I will speak in general terms.

First, a balanced design with push-pull throughout will greatly improve 2nd order distortion and will also improve 3rd order distortion, although to a lesser amount.

Second, 2N3904 transistors would not be my choice for a high performance design. I would go with a part with much higher ft, perhaps the BFR95/PLP used in the first stage.

Third, you will find that there is an optimum idle current for 2nd and 3rd order intermodulation for each transistor type, and that 2nd and 3rd order intermodulation performance is not optimized at the same current. This is where a real RF transistor is beneficial as the data sheet will have some plots of 2nd and 3rd order intermodulation versus collector current.

Fourth, in a loop preamplifier, noise figure is very important and resistance feedback amplifiers are not the topology of choice for low noise figure amplifiers.

You might look into the M0AYF loop preamp circuit. It is a simple
broadband single-turn loop with a balanced preamp circuit
that is easy to build and gives very good results.

73 - Todd WD4NGG

Hi all,

this is the group where all the loop gurus lurk, so I think this is the
best place where to ask suggestions
about this simple schematic of a preamplifier I have just built for my
single turn loop, made of 3/8" copper
tube, about 1.3 meter (4.8 feet) in diameter, which in my intentions should
cover from 60 kHz to the
21 MHz ham band.

Dean,

Don't spend too much time reading that article, the information, good, or bad, will not help you build a FSL. I am going to give you a link to a article that I have posted on this site, which has a ton of information that should be helpful to you if you want to build a FSL.

But here is my advise, if you want to build a FSL now, or later, then buy now the 62 x 12 X 4 mm Russian ferrite bars now listed on eBay, as they will not last much longer. There were 3 suppliers of the bars, which have been cleaned out and there is now only one left, he had the higher prices that is why he still has bars left. Even at his current prices they are a bargain.

So you need to ask yourself, do I want a single band, or a dual band FSL. If it is a single band then you only need to be 2 bars wide (5"), if you want a dual band then you need to be 3 bars wide (7.5"). It has been proven that a 8" FSL is a good performer, so shoot for that. So if you are going for a single band FSL you will need 86 bars, if you want to go for a dual band FSL then you will need 129 bars.

Hi John,

It probably does not mean anything if you have enough space between the turns, but when you have the windings next to each other, then distributed capacitance does become a major factor. Litz wire does have less distributed capacitance when the windings are butted up next to each other, then does standard wire.

Okay, I'll bite. What does Litz wire have to do with
distributed capacitance?

Hi,
I read your post, and it sounds very familiar. I just built a 1 meter loop using 3/8" copper tubing, and it works extremely well, but...I don't think that you will get that large of a range with it. I used a dual gang 365pf variable capacitor, and with both gangs switched in, it bottoms out around 3.2 mHz. And with only one gang switched in, it tops out just above the 20 meter ham band.....about 14.5 mHz. One thing that I found though, it tunes so sharp, that I had to put a 3:1 tuning reduction unit on the capacitor to be able to tune it.

Yes, use of Litz gives less distributed capacitance when wound with turns directly side by side with no spacing between turns, compared to non-Litz wound side by side with no spacing between turns. Those of us who have made LF and MW FSLs have observed this every time a comparison was made. Non-Litz turns need to be spaced to get the same tuning range for a given size tuning capacitor. (A small group of experimenters began experimenting building FSLs once Graham Maynard's article became available--Kevin Schanilec, Gary DeBock and myself, and later, Everett Sharp joined in. Results were posted on the yahoo ULR group. We quickly found that Litz gave significantly better results--higher output and sharper tuning--than non-Litz and never used non-Litz after that. And using the biggest Litz available (660/46) gave the best FSLs, even at LF, where /46 Litz isn't supposed to be optimum. Litz can be spaced to get the absolute lowest distributed capacitance for a given coil diameter, but we wound most of our Litz FSLs with no spacing. Everett Sharp probably has the most experience building FSLs with spaced-Litz.) (Everett Sharp was going away on vacation shortly and may be already gone--he may not be able to give any more replies for awhile.)

Just my $0.02.

I have not built an FSL but I've built many (on the order of 100) air and ferrite core tuned loops over the years. I even built a 3' spiral loop with 22 Ga. Sterling Silver wire back when Silver was cheaper.

Distributed capacitance is pretty easy to measure with a signal generator and oscilloscope and a bit of Math. A loop antenna is basically a parallel LCR tuned circuit whose input is the magnetic component of the local RF field. If there's no tuning capacitor hooked to the coil it still has a resonant frequency that can be determined easily enough. Finding the self resonant frequency and then putting a known value capacitor across the coil and measuring that resonate frequency, with a little Math, the distributed capacitance of the coil can be derived.

When working with a new design I use solid or stranded insulated wire with as close to the same diameter as the Litz I plan to use on the final winding to save $ so I've made quite a few measurements of distributed capacitance. What I've found is that with air core loops with 1/4" or more spacing the difference is negligible and with close wound rods it can vary from about 25-35% less with the Litz compared to enamel coated solid wire to 10% or so MORE with the Litz compared to some vinyl coated stranded wire with the same outer diameter as the Litz. Distributed capacitance will lower the Q and narrow the tuning range.

It's my understanding and experience that the main advantage of using Litz wire is it's lower resistance to RF current. Most papers and articles I've seen about resonant loop antennas ignore the "R" component of the resonant circuit. High resistance in the wire will effect Q much more than distributed capacitance in a carefully wound coil.

Litz has a lower resistance because of what's called the Skin Effect. From just above audio to about 5MHz or so the RF current tends to concentrate on the outer layer of the conductor. Litz wire has more "surface" than solid, stranded wire acts like solid wire at RF if the strands aren't insulated from each other.

I think one of the main reasons the FSLs have such good Q is the monster Litz has very low RF resistance and there's only about 40' of it as compared to 65-80' on an average MW air core loop. The large magnetic aperture probably accounts for the sharper nulls.

I haven't seriously considered building an FSL since I have to get my loop antennas at least 25' above ground to get away from the local RF racket from my neighbors. Remote tuned and rotating active loops are what I've been working on and the weight and wind resistance of a

housing large enough for an FSL make it impractical.

John,

Litz wire reduces the impact of the skin effect and the proximity effect. So for a piratical explanation I have just wound a 18 turn coil with standard solid 18 gage wire, close wound, on a 7.5" FSL and I find the tuning range (using a 10 to 381 pf variable capacitor) is 1200 to 400 KHz. Now I rewind a 18 turn coil, close wound, on the same 7.5" FSL using 660/46 Litz wire, and I now find the tuning range is 1850 to 405 KHz. So my question to you is if it is not higher distributed capacitance using the solid wire over that of the Litz wire, then what is it that is causing the frequency, at the high end of the band to be lower and having less tuning range? This is not theory, this is what I see from a piratical stand point. I am sure that if you want the theory behind it you can find it somewhere here on the web. (I am not skeptical, I am a believer)

I am not an expert in this field, far from that, but how about the dielectric properties of the coating of each of the Litze wires. Although, now I come to think of it, this would increase the capacitive coupling.

Or is this nonsense?

Cor Beijersbergen

John,

Litz wire reduces the impact of the skin effect and the proximity effect. So for a piratical explanation I have just wound a 18 turn coil with standard solid 18 gage wire, close wound, on a 7.5" FSL and I find the tuning range (using a 10 to 381 pf variable capacitor) is 1200 to 400 KHz. 9558. Re: [loopantennas] fs loop article

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-01-06 12:14:37 UTC
From: everettsharp@aol.com
Topic: 9541 Message: 9558

Hi Tim,

After I posted my article a few months ago on the stacked toroid loop stick experiments, I
had mentioned that I would like to do more experiments, but this time
using FT 240-61 toroids, rather than the FT 140-61 that I used, but that I did
not know if I wanted to spend that much money to try them.

As a result of those comments I got a direct email from a Eb Killer where
he did some experiments with the FT 240-61 toroids and here is the info that
he sent me.

The current coil configuration I arrived at is 2x26 turns
of 660/46 litz on 2 genova S40130 styrene couplings,joined
with a 1" wide 3" pvc pipe to form a 3.5" x 7.5" long bobbin.
The coils ate spaced .75",wound in same direction.
Connected parallel the inductance is 210uH with the 24" rod.
This results in a 0.55" spacing of coil over ferrite.

I tabulated the following data at 650kHz,
rod Q mv normalized
to Q 1000
7.5" 1385 180 mv 144.4

12" 1320 270 mv 204.5

24" 1100 396 mv 360

36" 1050 450 mv 428.5

Amidon 7.5"x.5" 680 76.5 mv 112.5

1 meter loop 155 292 mv 1884

So the reason that I bring this up is Eb was planing on setting up a 24"
long stacked toroid loop stick outside his house and use varicaps to tune
it. Maybe something like this might work for your application? I just don't
know how it would compare to a 8" FSL in performance, which would be a lot
less expensive. Eb got a good deal on his toroids, but if you had to buy them
from kit parts, @ $9 each, it would cost $432. Another option is to build
one using the FT 140-61, it would take 60 of them, but would only be $130.
The 15" one that I experimented with did work very well and it out
performed a 2' air-core box loop. As I had mentioned in some of my earlier post I
have ordered 60 more of the FT 140-61 toroids to do some more experiments
with, but this time with a longer rod, 23" to 24" long and with multi-coils.
You would not have much wind loading with something like this and you
could put it inside PVC pipe to protect it from the weather.

Finding the self resonant frequency and then putting a known value capacitor across the coil and measuring that resonate frequency, with a little Math, the distributed capacitance of the coil can be derived.

When working with a new design I use solid or stranded insulated wire with as close to the same diameter as the Litz I plan to use on the final winding to save $ so I've made quite a few measurements of distributed capacitance. What I've found is that with air core loops with 1/4" or more spacing the difference is negligible and with close wound rods it can vary from about 25-35% less with the Litz compared to enamel coated solid wire to 10% or so MORE with the Litz compared to some vinyl coated stranded wire with the same outer diameter as the Litz. Distributed capacitance will lower the Q and narrow the tuning range.

It's my understanding and experience that the main advantage of using Litz wire is it's lower resistance to RF current. Most papers and articles I've seen about resonant loop antennas ignore the "R" component of the resonant circuit. High resistance in the wire will effect Q much more than distributed capacitance in a carefully wound coil.

Litz has a lower resistance because of what's called the Skin Effect. From just above audio to about 5MHz or so the RF current tends to concentrate on the outer layer of the conductor. Litz wire has more "surface" than solid, stranded wire acts like solid wire at RF if the strands aren't insulated from each other.

I think one of the main reasons the FSLs have such good Q is the monster Litz has very low RF resistance and there's only about 40' of it as compared to 65-80' on an average MW air core loop. The large magnetic aperture probably accounts for the sharper nulls.

I haven't seriously considered building an FSL since I have to get my loop antennas at least 25' above ground to get away from the local RF racket from my neighbors. Remote tuned and rotating active loops are what I've been working on and the weight and wind resistance of a housing large enough for an FSL make it impractical.

I didn't know that. Is this a fact you have measured, or a
claim you have read, somewhere? (I'm sceptical.)

From: Jack Smith
Topic: 9541 Message: 9559

Fair-Rite's part number for FT-240-61 cores is 5961003801

A really quick search shows 50-99 lot unit price for these from Kreger Components is $8.10 each, dropping slightly to $7.89 in 100-299 volume.

http://www.kregercomponents.com/fair-rite-products/5961003801

Search for the Fair-Rite part number more and a better price may be found. And, you may negotiate a volume price break with Diz at Kits & Parts for that matter.

Hi Jack,

Thanks for the info, that would save $48, so now the cost is down to $384, still more then I want to invest to experiment with. I might get interested at $200. I think that they would make a very good loop antenna though.

Parallel inductance of the individual strands of the litz cable will increase the frequency for a constant capacitance and physical topology.

Thanks, Everett. That is the sort of experimental result I
was looking for.

One more question. Was the length (across the turns) of the
18 turn Litz coil the same as the length of the 18 turn
solid wire coil? In other words, was the 18 gauge solid
wire the same width as the (as wound) Litz wire?

Thanks to all who gave advice.

@Jack : yes, maybe better transistors should be used. And probably the amplifier has too much gain.
The PSpice simulation (FWIW) says that the gain from the loop input to the output is around 56 dB,
and such a high value is almost certainly the cause of the intermodulation, which, to be honest, is
not very severe, but at night it is quite perceptible.

@Todd : I have just given a look at the M0AYF schematic. Interesting, even if I do not understand
why he used a common emitter configuration, which does not exploit the very low impedance of the
loop, and makes shielding probably necessary. Anyway I will try to build it.

@Nick : it looks like yours is a tuned loop, in which case a coverage, as I would like to have, from
60 kHz to 21 MHZ is just impossible with a single variable capacitor. Mine is an aperiodic loop closed
on a very low impedance load, no tuning needed.

Another circuit I intend to test is the so-called noiseless Norton feedback, with a trifilar winding on
a ferrite bead, in a balanced configuration. If any of you has positive or negative experiences with
that, I would like to know them, thanks.

Are you saying, that for a given overall wire diameter (not
a given metal cross section), Litz has a lower inductance
per foot than solid conductor does? If so, do you have a
comparative experiment or manufacturer's data to quantify that?

The first stage needs to be very low input impedance, and Norton feedback amplifiers do not work well in that area. Very good for subsequent stages, though.

Somewhere in the group files section I have a design for a 2-stage active loop amplifier, named WidebandLoopAntennaAmplifierRevA.pdf that shows how to make wideband low input impedance amplifiers.

Did you mean "empirical"?

Series resistance will also lower the frequency of a tuned circuit. By what can be a rather surprising amount for a small resistance.

Scroll to the bottom of the followin link to resonance with impure components. The R is the series resistance of both the capacitor (usually negligible) and the inductor. Not the DC resistance, but the resistive component at frequency. So the skin effect is going to have an affect on this number.

<http://www.electronics-tutorials.ws/accircuits/parallel-resonance.html>

Fc = 1/(2pi) * (1/LC - R^2/L^2)^-2

Kinda hard to write that out in plain text.

In any case, where capacitance is high (and therefore frequency low), then the term 1/LC would tend to dominate over the term R^2/L^2. So 400kHz vs 405kHz.

But where C becomes very low, the term R^2/L^2 is going to dominate, and so with a larger Rseries, the frequency shift is going to be greater. I'm sure it doesn't account for all of the shift downwards for the solid wire, as with close windings I would imagine there will be more significant effects.

But - with only two samples, it is hard to say what all the major effects would be. Does that litz wire add up to the same cross section of copper? Or the same outside diameter? Or is it entirely different? How close to identical are the coils otherwise?

To get more consistent results, I might try cutting threads into plastic holders to get more consistent turns.

Distributed capacitance reduces the tuning range.

Losses in the core and wires are the Q killers. Litz wire has lower skin effect losses than solid wire.

If it were mainly distributed capacitance that lowered Q, then you could defeat that by using thinner solid wire and increasing the spacing between turns.

Hi Alberto,
As I understand it the M0AYF preamp is very stable and many people have had good results building it on perfboard, groundplane, or even design their own pc board for it. Nothing critical about the layout. No shielding necessary.

Steve Ratzlaff also came up with a good improvement to the circuit using a trifilar output transformer in place of the original bifilar windings. This gives higher output and better IMD performance over the original circuit.

John,

Please carefully re-read Everett's post where he has the experimental data which I quote in part as follows:

"... I have just wound a 18 turn coil with standard solid 18 gage wire, close wound, on a 7.5" FSL and I find the tuning range (using a 10 to 381 pf variable capacitor) is 1200 to 400 KHz. Now I rewind a 18 turn coil, close wound, on the same 7.5" FSL using 660/46 Litz wire, and I now find the tuning range is 1850 to 405 KHz..."

Unfortunately, no wire diameter is given but the inference is that the litz diameter would be the same or greater than the 18 gauge solid. Given the foregoing test data and knowledge of litz wire construction where there are parallel inductances and knowing the basic concept of parallel inductances, a reasonable technical inference can be made which explains the frequency range difference.

Now as to your question, I performed some toroid experiments a couple years ago with 12 gauge solid wire and approximately equivalent 12 gauge diameter litz cable on the same core type. Same lengths, same permeability etc.etc. Using a precision VNA, the upper break frequency was at a higher frequency with the litz than with the solid wire. The lower break frequency was shifted upward slightly as well.

Perhaps you could make your own measurements and report back to the group on your particular application.

As to litz wire (cable), not all "litz" is the same. There is a wide variety of mechanical 'lay', construction winding variations and weave angles which affect the distributed capacitances, inductances and resistances which affect the reactances/impedance of the cable. All of the foregoing affects the antenna resonant frequency range, Q, etc.
To your point and given the foregoing, litz diameter is not necessarily the predominant governing attribute.

Regards

John,

I don't know what the length was of the two wires, as I did not measure them. However, the cross section area of 660/46 Litz wire is nearly the same as solid 18 gage wire.

Thanks, Everett. That is the sort of experimental result I
was looking for.

One more question. Was the length (across the turns) of the
18 turn Litz coil the same as the length of the 18 turn
solid wire coil? In other words, was the 18 gauge solid
wire the same width as the (as wound) Litz wire?

Alex,

However, I would have to say that the Litz wire bundle of 660 strands, each with a insulated coating does make the bundle larger, how much larger, I don't know? I sure looks bigger, a lot bigger.

From: Tim Hills
Topic: 9541 Message: 9579

Heya Everett.

I've been using varactors for tuning loops for over 20 years now. ;-) There's pics of a couple of loops that have now been recycled in the "LoopyLoops" folder in the group photo section.

Most of what I've been doing lately is with active ferrite loops using a regenerative winding with gain controlled amplifiers. I have a rotator that was from a marine ADF that I modified and it's in the attic over the garage with a 23" round loop and there's a tunable 8" rod mounted 25' up with the local "pest" in the null.

My latest project is an electronically "rotatable" antenna using 3 rods mounted 120* from each other with the varactor bank switched between them. The two inactive loops don't interact (much) with the active one when the coils are left open and a tuned active whip is phased against the active rod. I can get a very nice front or back facing cardioid and by increasing the gain on the whip from that point a cloverleaf null pattern of varying angles. Not a perfect solution but a compact and lightweight one. Using 8 inch rods in a triangle the whole thing fits in a 12" diameter by 1 1/2" enclosure and weighs 3# or so.

I'm also using twin RG6, one carries the L.O. from a digital VFO and the first IF/mixer will also be built into the antenna housing at 10.7 MHz and fed down the other RG6. The vast majority of local noise is below 3MHz so upmixing at the antenna makes more sense technically and economically than trying to shield almost 100'. No point getting a good, clean signal just to have it swamped by garbage in the feed line. At night I have 5KW (1320) and 10KW (1140) stations beaming their night pattern into my back yard at 6 Miles each and a 400W-ND (1000) almost IN my back yard. Does make checking for intermod in my amps easy though.

The rods only have 16T of 100/44 Litz and the varactor bank is 2 sets of 26 parallel MVAM109s, about 6000pF at 1V and 380 pF at 9V. The windings are wound on a cardboard sleeve so I can move them for fine tuning. All can be tuned from 520 to 1750 KHz and have pretty narrow bandwidth (Q) without regen though I haven't taken any actual measurements yet. The whip uses a tapped torroid inductor and 8 more of the MVAM109s for tuning. The hand picked and matched varactors I'm using can be "pushed" to 10.5V so I can also cover the 160M band by overdriving the varactors.

The varactors were bought in a lot of 300, plus the 125 I already had and all were tested for capacitance at 5 voltages and for noise. If someone is using the surplus MVAM109s they should test them first. About 10% are noisy, another 10% or so have a poor 1V/9V capacitance ratio, low capactitance and poor V-C curves take out about 1/4 of them, leaving

50% pretty much unusable. About 30% of them are very quiet with a ~14:1 1V/9Vratio and perform well (noise) up to 11V, those are my preferred units and I'm using 60 of the 120 I have of them on this project

Doing this in my spare time when I can duck the Honeydo list so there have been lapses of a month in testing/building sessions so enough writing about it and back to the bench before she finds something that HAS to be done immediately.

The two inactive loops don't interact (much) with the active one when the coils are left open and a tuned active whip is phased against the active rod. I can get a very nice front or back facing cardioid and by increasing the gain on the whip from that point a cloverleaf null pattern of varying angles. Not a perfect solution but a compact and lightweight one. Using 8 inch rods in a triangle the whole thing fits in a 12" diameter by 1 1/2" enclosure and weighs 3# or so.
>
> I'm also using twin RG6, one carries the L.O. from a digital VFO and the first IF/mixer will also be built into the antenna housing at 10.7 MHz and fed down the other RG6. The vast majority of local noise is below 3MHz so upmixing at the antenna makes more sense technically and economically than trying to shield almost 100'. No point getting a good, clean signal just to have it swamped by garbage in the feed line. At night I have 5KW (1320) and 10KW (1140) stations beaming their night pattern into my back yard at 6 Miles each and a 400W-ND (1000) almost IN my back yard. Does make checking for intermod in my amps easy though.
>
> The rods only have 16T of 100/44 Litz and the varactor bank is 2 sets of 26 parallel MVAM109s, about 6000pF at 1V and 380 pF at 9V. The windings are wound on a cardboard sleeve so I can move them for fine tuning. All can be tuned from 520 to 1750 KHz and have pretty narrow bandwidth (Q) without regen though I haven't taken any actual measurements yet. The whip uses a tapped torroid inductor and 8 more of the MVAM109s for tuning. The hand picked and matched varactors I'm using can be "pushed" to 10.5V so I can also cover the 160M band by overdriving the varactors.

Hi Tim,

I can see that your projects are a lot more complex than mine, I try to keep mine simple and even at that they sometime get frustrating and more complex then I like. I wish I could put a antenna in my attic, but I screwed up when I had this house built by using foil covered sheeting my roof. I was for a energy conservation, it is suppose to reduce my heating cooling cost by 10 to 15%. At one time I thought about putting jumpers between the sheet and turning the whole roof into a antenna.

I have a article posted on this site with two 1 meter air-core loops that I made, both are wound with 330/46 Litz wire, one is for MW and the other is for LW. They are a hexagonal design and I made more like a good piece of furniture, using quarter sawn Red Oak that came out of a 200 year old tree. The Article is listed as The Hex Twins. They both work outstanding.

My project for the moment is another FSL, this one will be a 12" diameter and 7.5" wide, Tri-Coil Dual Band. Once finished I will dive into the Stacked Toroid, longer loop stick project. Right now I am try to get ready to go on a fly fishing trip to the Bahamas, I am leaving this next Saturday and still have a lot of flies to tie.

Everett

In a message dated 1/6/2013 1:30:28 P.M. Central Standard Time, thills@... writes:

Heya Everett.

I've been using varactors for tuning loops for over 20 years now. ;-) There's pics of a couple of loops that have now been recycled in the "LoopyLoops" folder in the group photo section.

Most of what I've been doing lately is with active ferrite loops using a regenerative winding with gain controlled amplifiers. I have a rotator that was from a marine ADF that I modified and it's in the attic over the garage with a 23" round loop and there's a tunable 8" rod mounted 25' up with the local "pest" in the null.

My latest project is an electronically "rotatable" antenna using 3 rods mounted 120* from each other with the varactor bank switched between them. The two inactive loops don't interact (much) with the active one when the coils are left open and a tuned active whip is phased against the active rod. I can get a very nice front or back facing cardioid and by increasing the gain on the whip from that point a cloverleaf null pattern of varying angles. Not a perfect solution but a compact and lightweight one. Using 8 inch rods in a triangle the whole thing fits in a 12" diameter by 1 1/2" enclosure

and weighs 3# or so.

I'm also using twin RG6, one carries the L.O. from a digital VFO and the first IF/mixer will also be built into the antenna housing at 10.7 MHz and fed down the other RG6. The vast majority of local noise is below 3MHz so upmixing at the antenna makes more sense technically and economically than trying to shield almost 100'. No point getting a good, clean signal just to have it swamped by garbage in the feed line. At night I have 5KW (1320) and 10KW (1140) stations beaming their night pattern into my back yard at 6 Miles each and a 400W-ND (1000) almost IN my back yard. Hi Tim,

After I posted my article a few months ago on the stacked toroid loop stick experiments, I
had mentioned that I would like to do more experiments, but this time using FT 240-61 toroids, rather than the FT 140-61 that I used, but that I did not know if I wanted to spend that much money to try them.

As a result of those comments I got a direct email from a Eb Killer where he did some experiments with the FT 240-61 toroids and here is the info that he sent me.

The current coil configuration I arrived at is 2x26 turns
of 660/46 litz on 2 genova S40130 styrene couplings,joined
with a 1" wide 3" pvc pipe to form a 3.5" x 7.5" long bobbin.
The coils ate spaced .75",wound in same direction.
Connected parallel the inductance is 210uH with the 24" rod.
This results in a 0.55" spacing of coil over ferrite.

I tabulated the following data at 650kHz,
rod Q mv normalized
to Q 1000
7.5" 1385 180 mv 144.4

12" 1320 270 mv 204.5

24" 1100 396 mv 360

36" 1050 450 mv 428.5

Amidon 7.5"x.5" 680 76.5 mv 112.5

1 meter loop 155 292 mv 1884

So the reason that I bring this up is Eb was planing on setting up a 24"
long stacked toroid loop stick outside his house and use varicaps to tune
it. Maybe something like this might work for your application? I just don't
know how it would compare to a 8" FSL in performance, which would be a lot
less expensive. Eb got a good deal on his toroids, but if you had to buy
them from kit parts, @ $9 each, it would cost $432. Another option is to build
one using the FT 140-61, it would take 60 of them, but would only be $130.
The 15" one that I experimented with did work very well and it out
performed a 2' air-core box loop. As I had mentioned in some of my earlier post I
have ordered 60 more of the FT 140-61 toroids to do some more experiments
with, but this time with a longer rod, 23" to 24" long and with
multi-coils. You would not have much wind loading with something like this and you
could put it inside PVC pipe to protect it from the weather.

thills@... (mailto:thills@sio.midco.net) writes:

Just my $0.02.

I have not built an FSL but I've built many (on the order of 100) air and
ferrite core tuned loops over the years. I even built a 3' spiral loop with
22 Ga. Sterling Silver wire back when Silver was cheaper.

Distributed capacitance is pretty easy to measure with a signal generator
and oscilloscope and a bit of Math. A loop antenna is basically a parallel
LCR tuned circuit whose input is the magnetic component of the local RF
field. If there's no tuning capacitor hooked to the coil it still has a
resonant frequency that can be determined easily enough. Finding the self
resonant frequency and then putting a known value capacitor across the coil and
measuring that resonate frequency, with a little Math, the distributed

capacitance of the coil can be derived.

When working with a new design I use solid or stranded insulated wire with as close to the same diameter as the Litz I plan to use on the final winding to save $ so I've made quite a few measurements of distributed capacitance. What I've found is that with air core loops with 1/4" or more spacing the difference is negligible and with close wound rods it can vary from about 25-35% less with the Litz compared to enamel coated solid wire to 10% or so MORE with the Litz compared to some vinyl coated stranded wire with the same outer diameter as the Litz. Distributed capacitance will lower the Q and narrow the tuning range.

It's my understanding and experience that the main advantage of using Litz wire is it's lower resistance to RF current. Most papers and articles I've seen about resonant loop antennas ignore the "R" component of the resonant circuit. High resistance in the wire will effect Q much more than distributed capacitance in a carefully wound coil.

Litz has a lower resistance because of what's called the Skin Effect. From just above audio to about 5MHz or so the RF current tends to concentrate on the outer layer of the conductor. Litz wire has more "surface" than solid, stranded wire acts like solid wire at RF if the strands aren't insulated from each other.

I think one of the main reasons the FSLs have such good Q is the monster Litz has very low RF resistance and there's only about 40' of it as compared to 65-80' on an average MW air core loop. The large magnetic aperture probably accounts for the sharper nulls.

I haven't seriously considered building an FSL since I have to get my loop antennas at least 25' above ground to get away from the local RF racket from my neighbors. Remote tuned and rotating active loops are what I've been working on and the weight and wind resistance of a housing large enough for an FSL make it impractical.

I didn't know that. Is this a fact you have measured, or a claim you have read, somewhere? (I'm sceptical.)

Have you considered going to balanced feedline and using cat6 network cable instead?

> The rods only have 16T of 100/44 Litz and the varactor bank is 2 sets of 26 parallel MVAM109s, about 6000pF at 1V and 380 pF at 9V. The windings are wound on a cardboard sleeve so I can move them for fine tuning. All can be tuned from 520 to 1750 KHz and have pretty narrow bandwidth (Q) without regen though I haven't taken any actual measurements yet. The whip uses a tapped torroid inductor and 8 more of the MVAM109s for tuning. The hand picked and matched varactors I'm using can be "pushed" to 10.5V so I can also cover the 160M band by overdriving the varactors.
>
I've been put off varactors by their poor Q. I'm going for the highest Q variable capacitor I can find, driven by an Arduino with a stepper motor shield attached. I was going to build a receiver to be driven by the Arduino as well, based on the Si4734 found in the Tecsun receivers (sparkfun have an Si4735 on a breakout board for $25) but I think in the short term, I'll just put my Drake R8B at the antenna end, and have the Arduino control that too, and command the Arduino from my computer using a USB DJ controller. The R8B gives the ability to use ECSS which is great for finding those weak carriers that you can sit on and wait to see if any audio appears out of the noise - can't do that with the Si4735 because it's AM/FM only.

> The varactors were bought in a lot of 300, plus the 125 I already had and all were tested for capacitance at 5 voltages and for noise. If someone is using the surplus MVAM109s they should test them first. About 10% are noisy, another 10% or so have a poor 1V/9V capacitance ratio, low capactitance and poor V-C curves take out about 1/4 of them, leaving 50% pretty much unusable. About 30% of them are very quiet with a ~14:1 1V/9Vratio and perform well (noise) up to 11V, those are my preferred units and I'm using 60 of the 120 I have of them on this project
>
Good information if I ever use Varactors. Thanks!

9584. Loop Antenna for WWVB LF Receiver

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-01-07 01:08:03 UTC
From: redsp
Topic: 9584 Message: 9584

Hi,

I'm making an all digital WWVB receiver with a goal of having the lowest power consumption possible. I am using an FPGA designed for very low power dissipation which has differential inputs I can use in a poor man's Delta Sigma ADC. I believe I can make it pretty sensitive with high processing gain to pull the signal out of the noise. Being on the east coast that will be important.

To minimize the power consumption I want to eliminate the RF amp. I have done a lot of research on the antenna and I think the shielded loop will give the largest signal without an amp.

After reading a number of web pages on loop antennas, a *very* large number of web pages, I decided to use a 2 foot diameter loop with 8 turns of RG-6 cable (solid copper core) as a reasonable compromise between ease of construction, size and effectiveness. This is 50 feet and I might add another 50 feet so I can use it without hacking the shield in the middle of the cable. I estimate a 2 foot loop with 50 foot of coax will give me a signal of approximately 30 uV from a 100 uV/m signal. To couple the antenna and receiver I am planning to use a ferrite loop with a number of turns of magnet wire as a transformer giving an even higher output voltage of 1 to 3 mV depending on how many turns I can get on the loop.

Any suggestions or thoughts?

Rick

Once it's done and tweaked I'll post the schematics.

I've found that sometimes things that work fine on the bench fail miserably when put in service and things that shouldn't work at all sometimes do.

I've used CAT6 in the past at other locations but with the high RF environment here at night filtering out the common mode interference can be problematic even with my R71-A grounded directly to the street side of the Copper water line going to the main over 100' away. I've had excellent results using the twin RG6 as a balanced feedline with the shields grounded and I have a source to get it pretty cheap.

Since I wanted a dual conversion unit anyway putting the first mixer at the antenna wasn't much more of a problem. The best way to win a fight is to avoid it so by moving the operating frequency above the majority of the noise I don't have to deal with it in the transmission line. I also have crystal filters for 10.7 MHz with 8 and 17KHz bandwidths that will be in the antenna enclosure.

I've found that the Q (and noise) of varactors varies a lot even in the same lot# of parts and depends a lot on the reverse current at the maximum rated voltage and the level on RF across them. That's why I'm using a low inductance and lots of varactors, fewer turns=lower RF levels and the low noise amps make up for the weak signal. Even the local pest only generates 50mV across the coil. Just an eyeball estimate using the scope and signal generator, -6dB points are about +/-6KHz at 950 KHz with a steep rolloff after that.

The worst loop I ever built was a square 4' LW loop with a single MVAM109. Everywhere I tuned I had signals, mostly intermod.:-[

The system is all analog with the exception of the VFO, an N3ZI DDS2 <http://www.pongrance.com/super-dds.html> and I am making heavy use of the BF904WR dual gate MOSFET that was designed for the cellphone industry but became obsolete almost as soon as it went into production. They take a steady hand to solder onto a circuit board but are very low noise and stable over the expected temperature range. The "receiver" end for now is my R71A tuned to 10.7MHz or a Soft66RF <http://zao.jp/radio/66RF/index_e.php> operating at the same frequency. Once the MW antenna is up and where I want it then I'll build the receiver end and probably incorporate the SDR module.

Everyone does things a bit differently and I'm building this system to do what I want it to do ;)

Hi Todd,

thanks for this further comment. When I said that maybe a shielding would be needed, what I meant is shielding of the loop, not of the circuit itself.
Given that with a common emitter configuration the input impedance is much higher than with common base, maybe the loop can gather some common-mode potential from the electrical field, which is not almost short circuited to ground from the very low input impedance of the amplifier.

Colline

I am measuring the following using an Array Solutions Antenna Analyser AM4170 with a 0.95m diam. loop made of 3/4 Aluminium tube.

Freq. 7.0MHz

The Equivalent circuit is:

Rs 6 Ohms
Xs 108 Ohms
Q 17.8

Lp 2.48uH

Kind regards

I would like to build a small wideband loop antenna with an internal amplifier. I was wondering if anyone in the USA sells either a kit or a prebuilt high quality amp?
I can build the loop myself, no problem there, it is the amp that I need.
I have seen Chris Trask's circuits and that would be my second choice because I would have to get all the parts and build it from scratch.
Thanks

Hi Larry

The wideband receiving loop antenna I would recommend is the M0AYF design, see http://www.qsl.net/m0ayf/active-loop-receiving-antenna.html

I built this design on stripboard and it really works very well. Before I had this loop 160,80 & 40 were so full of noise I despaired, but with this little antenna in place, these bands are once again just as good as they were when I first started out in amateur radio over 45 years ago, free from plasma TVs, switch mode PSUs etc. The parts are very easy to get hold of, nothing exotic. The hardest part is providing a waterproof housing.

Of course if you have the funds, then a Wellbrook amplifier, eg http://www.wellbrook.uk.com/antennashop/index.php?route=product/product&product_id=40 should also do the trick, but at a price !!

I suggest you use a pair of ferrite beads, side by side, as the core for the output matching transformer. Any low frequency ferrite shield bead. I think the next better form is a single high permeability ferrite toroid.

It will be smaller, lower loss and not pick up any other signals from the environment that get added to the received signal.

Here is what I am thinking about, with regard to comparing
Litz to solid (or any other two choices of winding conductor.

As long as the resonant Q of a the inductance of a loop and
with its own stray capacitance and a tuning capacitor allows
some actual math solutions, if two tuning cap values and two
resonant frequencies are available from an experiment, it
should be possible to calculate the actual coil inductance
and effective, parallel, stray capacitance. The additional
requirement is that, either the resonant Q is about 10 or
higher, so the losses do not appreciably affect the resonant
frequencies, or the effective losses must be calculable for

the for the loop at the two resonant frequencies.

The point being, that with a given coil, and two resonant frequencies, with two values of tuning capacitance, it should be possible to calculate the loop inductance and loop stray capacitance, by solving a pair of simultaneous equations for each coil.

So, it should be possible with these two resonant frequencies, per coil, with two values of tuning capacitance, we should be able actually solve for any coil's actual inductance and stray capacitance.

This technique should be handy to compare any two different construction choices (diameter, turn spacing, conductor strands, wire insulation, form material, etc.) to work toward an optimum (widest tuning range per dollar, highest Q per dollar, or whatever figure of merit you choose) design for any available coil conductor material and construction technique.

This solution rapidly takes coil design optimization out of the opinion phase and moves it into experimental science.

I mean either of these closed magnetic path transformers
will be smaller, lower loss and not pick up any other
signal, compared to a rod form (open magnetic path) of
transformer.

9600. Re: Is this preamp worth anything ?

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-01-12 22:51:01 UTC
From: lz1aq
Topic: 9546 Message: 9600

Hello Alberto,

1. You should have to use balanced design. It will increase the IP2 with 20 -30 dBm which is substantial difference. In these wideband designs 2nd order IMD are much more important than 3d order and they appear at lower levels of the input signal. Doubling your design as balanced will immediately improve IP2 and probably you will be satisfied. Assume also IMD from nearby FM stations.
2. The 1st stage transistors must have FT >200 MHz if you work up to 30 MHz. Since the circuit is common base, lower Ft can be used. PN2222A has very good noise figure and you will have no problems as a first stage up to 50MHz. I do not know whether low VHF noise automatically means low noise in HF or LF. So you can test different transistors (not in spice but by experiment) but do not expect substantial improvements!. The common emitter stages should have higher Ft and there you can use VHF transistors. I agree with Jack K8ZOA that you can get the best DC op. point from data sheet in order to minimize the IMD. In any case most of the IMD is comming from the last stages. You can look in my design
http://www.lz1aq.signacor.com/docs/wsml/wideband-active-sm-loop-antenna.\
htm
<http://www.lz1aq.signacor.com/docs/wsml/wideband-active-sm-loop-antenna\
.htm> as a simplest reference point and to have an idea what I am speaking about.
3. The input resistance of the amplifier is important as far as you need wideband design. Thus the loop is working in almost short circuit mode and the loop current does not depend from the frequency. If you do not mind very wideband design, you can work successfully with higher input impedance amplifier and you might have improvement in loop amplifier noise floor. Probably you will not need shielded loop up to 100 ohms input impedance. Moreover in balanced design this adverse effect is attenuated additionally.
4. In your spice model you can change the loop model with Norton equivalent circuit with current source. This has the advantage to be frequency independent and make the analysis more convenient. Otherwise to get frequency response of your amplifier in spice you should have to involve frequency dependant voltage source (voltage must increase linearly with frequency)
5. If you planning to listen LF you must avoid many transformers (as you do). They are wonderful in order to reach good CM rejection and low noise - but very low frequency response is difficult to be reached (or I can not reach : - (. In any case use ferrite cores with u>10000 and you probably can go down to 50 KHz preserving 20-30 MHz upper frequency. But the best way for LF is not to use any transformers.

6. Defining voltage gain in these amplifiers is not suitable.
Define in spice: GAIN = V_out/I_loop to get the curve of antenna
factor. The gain of these trans-resistance (or transconductance?)
amplifiers must be 700- 800 V/A (or Ohms). With this gain and 1 sq.m
single turn loop you will have antenna factor around 0 dB /m which
means 1 uV/m field will give 1 uV output voltage. Assume loop
inductance between 2 to 5 uH for single turn loop and current
source of 0.7 to 2 nA (for 1 uV/m field intensity) and you will
get the output voltage directly in uV. I roughly estimate that your
amplifier gain is somewhere in this region. In any case the
minimal gain should be determined mostly from the noise floor of
your RX. The output amplifier noise without antenna should be at least
several dB higher than the RX noise floor. Connecting the amplifier
to RX (without antenna) should increase the RX output audio noise.
7. Be aware that when the common base amplifier is working with
very low resistance of the source, the noise figure is
degraded substantially. So in very low frequencies, where the loop
impedance becomes very low the output noise increases. Probably you
should have to use loops with larger inductance (larger size or even
with several turns which is not very good from other point of view)
but this has to be tested. My own experiments show that for
LF it is easier to built electric rather than magnetic wideband
antenna. But there are other problems with electric antenna e.g. lack of
directivity and increased conducted noise ..... so there is no free
lunch!

And at the end: thank you very much for your wonderful Winrad.

Ok, thanks. I'll probably go with the single toroid because I want to get 100 turns or so on the secondary to give me a larger output signal. Might be a little harder with two cores. What mu number would be "high"?

I'll likely get one from a broken PC power supply... if I can find a broken PC power supply. All the PCs I've scrounged from the trash lately have been working when I hooked them up, so I'm still looking.

One of the many loop antenna pages I visited, and the only one that used a core for coupling, used a toroid from an old PC power supply. He had a ton of them and used a bunch of the voltage switches for a power of 2 cap bank to tune the antenna. Very nicely done.

Any ferrite that has a measurable resistance when touched with the points of ohm meter leads will probably have usefully high permeability at 60 kHz. If you have several cores to choose from, lower resistance generally indicates higher permeability. The stuff made for megahertz signals almost always shows an unmeasurably high resistance.

Yes, power ferrites are pretty good transformer material for 60 kHz signal use. But many of these are not ferrite, but powdered iron, low permeability, energy storage cores. Those are almost always painted with bright colors, as a material code. Some ferrite is also painted for insulation purposes, but not usually. You can nick the paint with a file for the resistance test. Ferrite is also black and glassy hard, while the powdered iron material is usually light grey and soft enough to nick with a file.

Cup cores (pot cores) and other two piece transformer types are very handy for comparative experiments, because the coil is wound on a bobbin (that can be swapped out). You just have to find core pairs that do not have a gap between the center pegs (which lowers the effective permeability).

I have a pretty good collection of such things, so if you contact me by email, I may be able to send you a little kit of parts to play with.

Sounds like useful info. This is stuff I should know about, but have never worked with.

Actually, after I sent my last reply I was doing a search for a toroid core and found an interesting video on toroidal core winding. I couldn't quite see how the machine worked in the video, so I'll watch it again full screen to see if I can pick up some details.

While watching the video, I realized that this is pretty much the same as a current transformer. After doing a search on Digikey I found a number of secondary coils that should do the job. But then magnetics are not my strong suit. Certainly it is a lot easier to buy one of these for $3 plus shipping than winding my own core. Do you think this would be a useful transformer for a 60 kHz antenna?

http://www.digikey.com/product-detail/en/PE-51688NL/553-1546-ND/2265978

Or should I find a good core and wind it myself? My goal is to get the highest output voltage so I think I just need to use as many windings on the coil as practical. It will be driving a very high impedance input, not a coax.

From: dannibou
Topic: 9604 Message: 9604

Hi to members of this group. I know it's a bit off topic but it is related to antenna and preamp circuits. I own several ferrite rings that I could use to build antenna preamp but the problem is that I don't know what it's their permeability. I know that it's important in some circuit and I wonder if it exist a way to know the caracteristics of them. I would like to classify them separately for future project. Any ideas? Sorry if my english is not as good as I would have liked.
Thanks
Danny

There are two basic core material categories. The powdered iron group (actually iron or one of several high permeability alloys, like Sendust or moly Permalloy) or ferrite (a solid ceramic material that has low conductivity compared to metals and high permeability, compared to most ceramics).

http://www.mag-inc.com/products/powder-cores

The powdered cores are often used in power supplies, for circuits that need energy storage inductors, like DC filters or flyback transformers (where energy is first stored in the core and then released into the output). These cores are often painted in solid colors, often with one side a second color, to encode their material and permeability.

Unfortunately, there is no universal code used by all manufacturers, so knowing the color, without knowing the manufacturer only narrows the possibilities. Measuring the inductance of a test winding is often needed to be sure of the permeability. An inductance meter or bridge is very helpful for this work.

These cores are made of metal powder clued together with a filler and binding material and are usually light grey color (for the higher permeability, mostly metal ones)to tan (for the mostly filler, low permeability ones), under the paint.

http://www.micrometals.com/materials_index.html
http://www.qrz.lt/ly1gp/amidon.html
http://www.rfcafe.com/references/electrical/toroid.htm

Ferrite comes in two common flavors. Nickle zinc ferrite (NiZn) is used for most high frequency applications. It has medium permeability (tens to hundreds), very high resistivity (usually measures off scale high, if touched

with ohm meter probes) and has less flux capability than the lower frequency materials. The lower frequency and power materials are mostly Magnesium zinc ferrite (MnZn), and generally have permeability ranging from hundreds to tens of thousands. They are also a lot more conductive, with conductivity generally lower, the higher the permeability. You may get an ohm reading of thousands to hundreds of ohms if you touch them with ohm meter probes.

All ferrites are black to dark grey and break like glass. They can be used for transformers in ungapped forms, including two piece parts that have polished mating surfaces, or for energy storage and linear inductors, if a gap is made between mating halves in the magnetic path.

When I wind toroid cores, I find a wooden dowel much smaller than the hole in the core, usually a foot or a little more, long. I notch both ends and wind the wire between these notches, to make a supply of wire I can easily pass through the core. This long bobbin makes it a lot easier to pass a supply of wire, multiple times through the hole in a toroid.

Most current transformers are made with metallic ribbon cores that are optimized for line frequencies, though some are made of ferrite for switching power supply CT applications. The ferrite ones might well serve for the secondary of a 60kHz transformer.

> http://www.digikey.com/product-detail/en/PE-51688NL/553-1546-ND/2265978

That one is certainly made for your frequency range.

I think that CT might be a good place to start some experiments. But keep in mind that your pickup coil is not a zero ohm voltage source, but has some impedance. That impedance will limit how high you can jack up the voltage

with a transformer, before the transformer starts to load down the voltage from the coil. But you might push it a bit higher by resonating both the coil and transformer with capacitors (reduce their usable bandwidth, but peak the response around the desired frequency).

Do you have an oscilloscope or other means to measure the signal you are working with? I made a field generating coil, to produce a stronger drive signal than WWVB, for such experiments, so I had enough signal to make accurate, comparative measurements.

Hi Chavdar,

many thanks indeed for all of your suggestions, which make a lot of sense.
Yes, I have decided that, whatever the final form of my preamplifier will be, it will use a balanced design, like your schematic, which I was already aware of.

There is one thing I am just considering... given that there are new MMIC amplifier on the market which exhibit strong resistance to intermodulation and low noise, I am thinking that maybe a couple of them, in a balanced configuration, could work rather well.... for example, I saw the specs of the GALI-7+ which look very interesting ...

https://dl.dropbox.com/u/15089947/Gali7.png

Features :

? InGaP HBT IF and RF amplifier
? frequency range, DC to 1 GHz, usable to 4 GHz
? high gain, 25.1 dB typ. at 100 MHz
? up to +19.2 dBm typ. output power at 100 MHz
? high IP3, +38 dBm at 100 MHz
? low noise figure, 2.7 dB typ.
? unconditionally stable
? low thermal resistance
? transient protected
? low cost $1.85 (qty. 1000)
? protected by US patent, 6,943,629

Note the +38 dBm IP3 and the noise figure, 2.7 dB

Are there substantial reasons why not to use a couple of such devices for a preamplifier ?
I have no experiences in the use of such components, so I am asking here those who maybe have already used it to know if there are hidden drawbacks...

And glad that you like Winrad !

Looking at the shape I realize these transformers may just be coils rather than toroids. Will that make a difference?

Yes, I have an oscope and a signal generator that can make a 60 kHz sine wave. I will be testing the antenna shortly. There are a lot of facets to this project and I tend to bounce around between them rather than work solely on one part at a time.

The load (receiver input) will be very high impedance (megohms), so I can't imagine a 10 ohm coil resistance will matter much. I will look into tuning the transformer output as

well as the antenna coil. Thanks.

No, I think the one you linked to, below, has a high
permeability, ferrite, toroid core. Without a core, it
would have an extremely low output.

(snip)

It ,may be megohms at DC, but there is also stray
capacitance across that 200 turn secondary (most of it,
inside the CT, itself. If you use a single turn primary to
get the full 200X voltage multiplication, that capacitance
looks 200^2=40,000 times larger, across that one turn
primary. So several primary turns may be a more optimal
load for the loop. Experiment will tell, especially if you
sweep frequencies near 60kHz. You may be able to peak the
response almost just by selecting the right number of
primary turns, leaving only a little need for additional
resonating capacitor.

Don't forget that that 1:200 transformer will also reflect a
1 megohm amplifier input impedance down to 25 ohms across
the primary.

Are you sure the reflected image of the resistance and capacitance will be proportional to the coil ratio squared and not just the coil ratio? I see I need to dig into this a bit more.

Quite.

Voltage changes by turns ratio and current by inverse turns ratio. But impedance is the ratio of voltage divided by current, so the turns ratio comes into the impedance ratio, twice (second power).

Hello Alberto,
There are no substantial reasons not to use a couple of such devices; especially in this case probably you can use them as a final amplifier. The loop amplifier is not a very standard case so with ready made modules sometimes you can not reach easily the desired parameters. The benefit of using modules is that they save you design time (no spice modeling etc.). But there are no rules and every design is a compromise between controversy requirements: parameters, price, availability, and not the last the designer's preferences which sometimes are not very logical. There is also conservatism and probably we should more often look at the new data sheets of the chip producers.

Hi Alberto,

Most of the preamp modules are designed for 50 Ohm matched input.
This is not optimal for the loop.
There are designs published that use high speed opamp in an inverting configuration, which is supposed to give a very low input impedance and avoid using discrete transistors. I attempted to build such amplifier and had difficulties to keep it stable.
My impression is that Chris' and Chavdar's designs that use discrete transistors are the way to go. Chris' "secret sauce" is transformers, which require more build efforts but seem to improve the parameters.

What are peoples feelings on the front end of this circuit?

http://users.tpg.com.au/users/ldbutler/ActiveLoopConverter.htm

I want q-multiplier ability. The best loop I ever built had a FET q-multiplier attached to the tuned circuit, but the feed to the receiver came from a smaller single turn, closer to the centre of the loop (Q Multiplier and Spiral Loop Antenna - Maynard - Practical Wireless March 1981). I am considering using NE5534's in a balanced configuration.

Discuss.

In general, the noise figure of even the best op amp is nothing to brag about compared with a properly designed discrete transistor design with noiseless feedback.

Some of that concern goes away when using a tuned loop with, in effect, a step up transformer via the coupling loop. The transformer, in effect, provides "noise free" voltage gain that must be factored into the composite noise figure equation.

The referenced circuit with op-amp front end is probably fine for the frequency band in question, < 500 KHz where atmospheric noise is predominant.

You've given me something to think about. What about the inductance of the secondary? How does that impact the primary circuit? Wouldn't that affect the tuning of the primary?

I fired up my scope today and found it is not working properly. The horizontal sweep seems to be a bit diminished. So I may be in the market for a new one. I also have an equally old HP signal generator which seems to be outputting what looks like a rectified sine wave on the scale that covers 60 kHz. The lower ranges look fine. I took the cover off (for the first time) and it has a bazillion discretes and a number of transistors. Not sure where to start fixing it. Maybe I need a new sig gen as well. :(

(snip)

According to the data sheet, the 200 turn winding has at least 80mH inductance. That means a single turn primary will have only 1/40,000th of that or 2uH inductance. This gives you an idea of the core they used, since you know roughly the size, and that it produces about 2uHy with one turn.

But you can add as many turns as you wish to the primary to raise the primary inductance and lower the turns ratio.

You can also tune the inductance with capacitance. This might work best with a series capacitor between the loop and the primary, and a parallel capacitance across the secondary of the transformer.

Sorry to hear about your test equipment.

(snip)

The core is probably something like Fair-rite part# 5975000301.
http://www.fair-rite.com/cgibin/catalog.pgm#select:onepart
It produces at least 2.16 uH with one turn.

To build an amplifier for a tuned loop AND LF band is easy, meaning that there is a wide range of components and topologies that would not limit the system performance.
Wideband untuned loop + HF band is a very different application, where the choice of components and amplifier topology is critical, because they will define the system performance (signal to noise and signal to unwanted signal ratios).

One does not normally use a loop to locate power line noise.

The method used is to use a non-directional antenna and a receiver that tunes to VHF/UHF frequencies. Driving (or walking) along the suspected power line, note the noise level and increase the frequency until the noise can just be heard. Repeat. In the case of a severe noise source, you may be able to hear it at 800 MHz or above.

This will get to you the pole usually.

To determine the hardware that may be bad, several techniques are used. One is a noise receiver operating around 200 MHz with a 3 element yagi. Another is an ultrasonic receiver. Yet another is a thermal imaging camera. In the best case these will identify the defective hardware.

Never a loop.

I used to do this for a living and also have worked with the local power company to solve a problem plaguing my reception.

Gene,

I've tracked down several noise sources with a small portable AM radio tuned to a "dead" spot in the band. I use a DX-399 but any handheld AM radio should work.

It works surprisingly well for many types of noise and the internal loop can null the source giving a bearing. YMMV since my interest is primarily MWDX but you might want to give "cheap and easy" a try before getting more elaborate.

An AM radio even a little handheld portable does the job too... I have no problem telling what poles and stores are culprits for RF noise along my commute to and from work. Never used it to chase down wall warts but it would probably work for that too.

I used to use an am radio to check big rectifiers in medical equipment.. It was one of those multi-fin type rectifiers. It let me know if it was arcing (time to replace it)

But for higher frequency switching noise, maybe an fm radio.. I haven't tried it.

One time I was using headphones with a mike on Skype... came too close to a CF bulb and wiped out the communications with noise on the Skype channel I was one. Turned the mike off and I was fine.

The latest CF bulbs and even the LED type bulbs are great sources of noise, if your looking for something near. I think there's more RF pollution in a household than there is from power lines. But given the past "Sandy" storm and subsequent wind storms, there's lots of weakened wires and transformers.

The problem with using a loop to track down strong interference sources on a power line is that the power line is a long antenna with standing waves.

Hence either it's impossible to obtain a null -- noise arrives from multiple sources at different angles -- or the null is a false direction (vector sum of multiple signals) or there is loop error because the loop null azimuth is only valid for vertically polarized signals.

I've seen one case where a loop gave a perfect null on a 500KV line transmission tower at 3.5 MHz. In fact, the noise source was 5 miles away at a switching substation where a wavetrap was arcing. You could even hear the arc, but a lot of time (and money) was spent poking around the wrong site. As best we could figure it out after the fact, it was a combination of a standing wave and an induced noise current on the transmission tower.

Yes, an AM radio can help, if that's all you have. But it's not the tool that professionals use. Rather, they use an "interference locating receiver" -- Sprague used to make one just for the power company RFI business -- that tunes up to a few hundred MHz. Drive along the line watching the S-meter and as the noise level increases, increase the frequency. The peak of frequency and strength is the source.

This method can fail, but it's many, many times more accurate at pinpointing the offending distribution pole.

We could hear the arcing wavetrap putting out noise with the receiver tuned to 1 GHz, by the way, when within a hundred feet or so of it. Trying to DF it with a loop at 3.5 MHz was useless.

The loop led you to a tower on 80 m but if you
didn't hear the noise on UHF, you would have
known it was probably a false source. I would
not use the 80 m loop while under the power line
since you know the noise is propagating down the line anyway.

Actually, he said "One does not normally use a loop to locate power line noise."

Loops have a directional null, so maybe a bit more art is needed in using one to track down noise.

Would something as seen here work?

http://www.youtube.com/watch?v=SHjBcNtt5hA

The Degen makes for a halfway decent portable receiver for this purpose too ..

Some observations and conclusions I've come to in hunting down noisy distribution-level (as opposed to HV Transmission) poles and lines:

(1) Directly out, 90 degrees from a power pole, anything radiated from the voltage conductor 'wires' is cancelled. Think: T-top loaded vertical. Hint: The T-top does not radiate, it's a top load ...

(2) The majority of radiated EMI from a power pole observed from the street is from the *ground* wire coming down the pole (if it is properly connected at both ends.) Note I said majority, there are a few exceptions ...

(3) Using a tuned vertical loop also ignores any incidental horizontal components ... and since wire just hanging by itself isn't going to the the 'source' (compared to loose hardware, arcing surge suppressors, bad insulators) it's the POLE with the source one is interested in hunting down.

(4) One is better off hunting with a radio that covers the same *band* where your acring interference is showing up ... many sources out there on the poles have their own unique individual 'bands' they make noise in, especially when up close! Once be easily deceived if not careful to establish coincidence between a found noise source out in the field and a receiver in the shack.

Topic: 9622 Message: 9634

I converted my HF loop from a shielded one to an unshielded floating loop with magnetic coupling. Here is the picture of the HF loop and Yachtboy general coverage HF RX. Also the pix shows 440 MHz yagi and Yaesu VX5R I listen on 441.7 MHz AM mode to pinpoint the noise once the loop gets me close to the source.
http://egpreston.com/K5GPloop1.jpg
The non grounded and floating large 13 inch loop is just a piece of RG8 coax with shield and center wired together and in series with a 360 pf variable cap. Wire could be used instead of the coax, but the coax was already there and is stiff enough to not need extra supports. The loop naturally tunes from 8 to 28 MHz. There is an extra fixed mica cap in parallel with the variable cap that has about 250 pf and allows the loop to tune from about 6 to 9 MHz when clipped across the variable capacitor. The 3,5 inch diameter (not critical) magnetic pickup coil is shown on this picture:
http://egpreston.com/K5GPloop2.jpg
Here is a picture of the connections between the large loop and the capacitor.
http://egpreston.com/K5GPloop3.jpg

How well does this floating loop design work? Initial testing revealed the loop tunes extremely sharp so the Q must be very high. The antenna has excellent gain and the reception of shortwave signals is much better than on the Yachtboy whip, but that's not saying much, since the little whip was not all that good an antenna. However you would not want to use this loop antenna for general coverage reception because it must be retuned each time you change receiver frequency. Note that you can pick up some signals on the inner small loop when the large loop is not in resonance so it should not be made too large.

After the loop was constructed this morning, I tuned up WWV on 10 and 15 MHz and the peaks and nulls were as expected with the direction of WWV being toward Colorado. The floating loop was very symmetrical, like the shielded loop was. However this loop is much easier to construct and get working than the shielded loop and uses fewer capacitors. The matching is achieved by the smaller loop being about 1/4th the size of the larger loop. The large loop is 13 inches diameter and the small loop is 3.5 inches diameter.

At noon my friend with the RFI problem returned my call and I went over to his house. He showed me what the noise sounded like on his HF receiver which was a soft mushy sound, not one that the noise blanker can take out. The noise was slightly louder on 24 MHz than 21 or 28. His HF beam gave the general direction as being north of

his house. He has distribution lines all over the place so the noise could be from any number of locations.

We went outside and could hear nothing on the VX5R and UHF yagi. So we fired up the HF loop and tuned around. At first we tried 21 MHz but his neighbors TV was generating noise. The HF loop indicated it was coming from his neighbors house. Then we went to 24 MHz and still could hear the TV. We tuned up to 26 MHz and the power line noise was heard as a light signal without the neighbor's TV interfering. There was also a sharp noise we didn't hear on his receiver in his house.

The loop indicated the noise was either north or south, but because his beam said it was north, we started walking north. The HF loop direction varied some as we walked along the street. There was a distribution line about 150 feet to our left or to the west which was also behind his house. We reached a point about a block north where the sound of the sharp noise indicated it was to the west. He said he was hearing that sound also on his vertical at this house but not on his beam.

At this point we were one block north and then we walked west following the location of the sharp noise on the HF loop. One block north and one block west the exact location on the HF loop could not be determined. However the UHF antenna on 440 pinpointed the sharp noise as coming from the pole one block north and one block west of his house. Returning back to the location one block north of his house we could clearly hear the softer noise source was coming from a pole one block north of this house. The sound was identical to what his HF rig was hearing at his house. The loop helped us to get in the general area and the UHF yagi pinpointed the two sources at two different locations.

So within a period of about 30 minutes we were able to pinpoint the two noise sources. The softer sounding noise he was hearing on his HF beam was on the pole one block due north and the sharper noise source he was hearing on his vertical was one block north and one block west. Going back to his house I checked the polarization of the sharp noise signal when in his back yard where the vertical is located and sure enough, the sharp noise source was almost completely vertically polarized. This explains why he was not hearing the sharp noise on his HF beam antenna.

My friend said that he would probably just sell his house and move out in the country where there are fewer power lines. He and I had struggled in the past on a similar noise problem and was becoming frustrated with having ongoing power line noise problems.

The conclusion is that the new floating loop has excellent performance and is easier to construct and tune than a shielded loop.

Good RFI hunting.

From: Chris Trask
Topic: 4637 Message: 9636

Lately there has been a good deal of discussion about the overall performance of active antenna amplifiers, and now that the number of postings has decreased I felt it was a good time to bring up an issue pertaining to the overall discussion.

In general, the overall quality of an active antenna amplifier encompasses the intermodulation distortion (IMD) and noise figure (NF) performance. For the vast majority of transistors, you can have one or the other but very rarely both simultaneously. To be specific, good NF performance is usually obtained at low collector (or drain) currents, while good IMD performance requires substantially higher currents, resulting in higher NF.

NF is a result of two distinct noise mechanisms, being thermal (Nyquist) and 1/f (shot) noise. The first of these is wideband noise that is generally of low spectral density. The second, however, is low-frequency noise that becomes noticable at frequencies below 100kHz to 1MHz and which increases with lower frequency. You might think that 1/f noise is of no consequence at HF frequencies and higher, however it modulates the bias current, which in turn modulates the inband signals in the same manner that SSB phase noise on local oscillator (LO) signals results in reciprocal mixing.

One method that has been reduced to practice to overcome the high NF of high frequency devices is to use a low-noise audio transistor to detect the low-frequency noise at the emitter, amplify and invert it, then couple it to the base. Ulrich Rohde introduced the method for reducing the SSB phase noise of microwave oscillators, while at the same time I employed it for reducing the NF and even-order distortion in common-base and lossless feedback amplifiers.

I have not seen anyone making use of this method for active antenna amplifiers, yet is is a method that has been reduced to practice for some time. This seems to be a good moment to remind the designer community of this so that we can see some new applications and an advancement in the art of designing active antenna amplifiers.

From: Mauno Ritola
Topic: 9622 Message: 9639

A bit off-topic, but I can confirm this from hard experience: the open air ADSL and telephone line coming to our house produced a big noise field for almost a decade. It was impossible to determine the exact point, where the noise was the strongest. And of course the local telephone company (telekarelia.fi , warm greetings to them ;-)) denied any responsibility for the noise and said it was impossible, because they can 'see' from the control centre, that everything is OK. Driving and listening from car radio it was exactly like you describe, getting stronger and weaker depending on where you were. The same with direction-finding it with portable radio and its ferrite antenna. The noise spread at varying strength all along the line for a couple of km and 300 m wide. It was the worst between 500-2000 kHz. Nothing helped. Last summer the ADSL connection began to break: short, irregular breaks. After a big fight and threats with extra costs the telephone company sent a technician to check the line. And yes, at one pole the outer layer of the cable had worn out during years, moving against the pole. He fixed it (probably by tape;-)) and most of the noise has been gone ever since.

Best regards,

Mauno

That's pretty much a sweet spot for ADSL transmission from the Exchange Office to your home. The noise (digital signalling) will vary by frequency as ADSL is a spread spectrum transmission system. The signalling is to be contained within the twisted pair cabling but we all know how that works - impedance changes due to bad splices, protectors, and aging facilities (corroded terminals) will cause the cable pair to go unbalanced and let the signal leak at various points along the cable.

Topic: 9622 Message: 9641

Back when I was using the phone lines for internet, I was constantly being dropped by Earthlink... The phone company changed the line to the house, and the pair from the street junction box was changed twice. The seconnd time the tech told me he was just recycling used pairs that were traded out for similar reasons. That's when I learned that the copper phone lines on the pole were no longer being purged with nitrogen or whatever gas they traditionally used. The lines were being allowed to decay as cell phone were becoming the major source phone links. This was also way before Bells Fiber lines. They're still fine for phone connections but crap for ADSL. That's when I switched to cable for Internet. Been fine ever since.

But it was noisy lines they gave me a very low input sig. Some freeware showed me that before I switched. Cable was a little bit of a problem in the beginning, but again a signal eval disclosed my house runs were part of the problem. They ran one line to my main computer location and then from there I had the house Ethernet switch. Never had a problem since.

The main idea is that the electrical and phone services (copper or fiber) are not always perfect. Trying to prove things can be a little of a pain. An sometimes they are purposely letting the old hardware go down the tubes because its obsolete. No advantage to being at the end of a network run. Your signal is just poor. Electric can be just as bad.... Who knows how far you have to go to prove your part of whatever circuit.

I work in the hospital environment. One hospital admitted they they had noisy power at their input transformer. It was beyond their control. And that meant they had to contend with all sorts of AC signal quality issues when it affected all the computer operated equipment in the facility.

I would think they electric company you choose has to contend with the same issues. You might buy your power from an environmentally friendly power company, but the power still comes over the same wires. If they're crappy so's your power no matter where it comes from.

The home can be just a bad a source of noise as the outside world. Maybe worse. The X10 appliance controls I use in my house are going down the tubes too... But its not the electric company's fault. With all the wall warts and switching transformers these days, I'm generating tremendous noise within the house on the lines and in the air. I'm sure I'd see plenty of noise. But I can't afford to filter every device in the house... I'd go broke with all the chokes I'd have to buy.... Filtering isn't exactly required for home environments. Ever since I did the environmentally correct thing and switched to CFs and LED lamps, my home control has gone down the tubes. Hate them if you like, but incandescents are becoming obsolete.

Even beyond power supplies, there's plenty of noise sources coming from all sorts of computer operated devices. What doesn't use a computer these days! Both copper and electromagnetic environments are challenges.

That's pretty much a sweet spot for ADSL transmission from the Exchange Office to your home. The noise (digital signalling) will vary by frequency as ADSL is a spread spectrum transmission system. The signalling is to be contained within the twisted pair cabling but we all know how that works - impedance changes due to bad splices, protectors, and aging facilities (corroded terminals) will cause the cable pair to go unbalanced and let the signal leak at various points along the cable.

Thank you Kevin and Phil for your comments. In my case the biggest problem was the broken cable, when it was fixed, most of the noise disappeared. I have got good advice from guys like Leif sm5bsz in the fight against noise and I think the situation is now good, please check online via sdrspace.com or Perseus network in eastern Finland. I hope we get underground fibre cable in the coming years, that will still improve the situation.
Thanks for the bandwidth and now back to topic.

Hi,
what is your opinion about the use of OPERATIONAL AMPLIFIERS as
AD8009 or OPA847, declared low noise and high IMD ??

I tried a single OPA847 inverting amplifier configuration with 10 ohm Rg and 1 Kohm Rf
(loop conncted to Rg via a 2uF multilayer capacitor)..
This seems to work, but I do not have sufficient instrumentation for measuring noise and
IMD, nor a standard loop to compare with mine.

thanks to all.

best regard

Just FYI I know of two loop designs with the OP847, they can be seen at:

http://wl1030.pa3ang.nl/content/ (This one is in English. You need to register here to get access, but that no other consequences)

http://dijkjj.home.xs4all.nl/download/bqc-wl1030xx.pdf (This one is in Dutch, but with lots of pictures, so you will understand anyway).

From: kd0qnm
Topic: 9648 Message: 9648

I know that for a mag loop, resistive losses are huge. Ideally, a single section of soft copper tubing or soldered joints are preferred.

That being said, has anyone measured how much loss actually occurs in a soldered vs unsoldered joint?

I ask b/c I am trying to build a portable mag-loop that can fit in the trunk of my car. Wanting to work 20/40 meters efficiently means my diameter ends up on the larger side. This makes a soldered loop self-defeating.

Any thoughts?

For a mag loop, unsoldered joints cannot be trusted at all. They are unacceptable, period.

For a large portable mag loop consider using a flexible copper element that can be folded
like copper flashing. I don't remember the formula but a certain width of copper
flashing is equivalent to round copper tubing. For example I think a 2-inch wide strip
of copper flashing is approximately equal to a one-inch diameter copper pipe. Plus
copper flashing is very light weight compared to copper pipe which would be another advantage for a portable mag loop.

A framework of PVC pipe that can be assembled in the field
can be built to support the copper flashing loop element. I built a transmitting loop using copper
flashing supported by a wooden frame years ago so I know the copper flashing idea works well.
If you use a long enough strip of copper flashing it can all be made using one
piece using no solder joints at all.

I think flared tubing fittings make very good electrical
contact.

I built a 40 meter loop out of 5/8 copper tubing that was about 6 ft dia as I recall. I used two copper clad pc boards separated by teflon screws for adjusting the spacing to change the capacitance. The loop was floating, not grounded. The 50 ohm match was achieved by adjusting the size of the inner loop connected to the rig. The pc boards were heavily soldered to the copper tubing to reduce the resistance of the connections. I have no idea what their soldered resistance was. The 1 to 1 swr could be achieved. However the frequency drifted when power was put to the antenna, indicating heating somewhere. The q was extremely high so the drift in freq due to heating was a problem. However it did get fairly good signal reports compared to a nvis dipole. I found it to be bulky and would not make a very good portable antenna for 40 meters compared to a whip. It was an interesting experiment however. It had low static noise and low noise from power line noise.

A metal pole might have induced currents causing losses. A wooden or plastic pole would solve that problem.

If you check out the plumbing department you will find all sorts of plumbing components. There are screw on type connectors that are soldered to the pipe and have a great deal of contact area and should provide a pretty low ohmic connection. Or have you already been down that road and this is what you are thinking of avoiding?

Another approach would be to join the copper tubing with short sections of soldered braid. This could be a fold point for storing and stiffened with a non-metallic sleeve which is slid over the braid when you want it to be a loop. The braid would be all soldered and so should have absolute minimum resistance.

Copper flashing -- what a great idea Todd.

Anyone know what the exact conversion from strip to tube diameter would be though? I would want to calculate out the required capacitance beforehand (so as to purchase the proper variable cap), and am not sure how to do so with a strip.

73, and tnx again.

If we are talking about resistance, I'm not sure it is that simple. The skin effect should behave differently on a flat strip than on a round tube. I think the tube will be a better geometry, but the strip will likely be thinner and so not as subject to the skin effect, depending on the frequency vs. the thickness. How thick is a copper strip? Or, how long is a piece of string?

As to the loop inductance, I don't think that will be significantly different from a pipe. In fact, the first formulas for inductance assume the coils are infinitely flat strips of conductor with infinitely narrow gaps between windings, hence the terms "sheet" inductance. All of the current flows in a sheet describing the coil. They have to make messy adjustments to the formulas to compensate for the geometry of "real" wires and tubing.

Is this really a practical approach? How many times can a copper sheet be bent before it creases and cracks?

Rick

Dan,
I cannot find exact conversion from copper strip to copper tubing but the general rule of thumb for antenna builders is one-half the width of copper strip is equivalent to a round copper tube. So a two-inch wide strip of copper is about the same RF Resistance as a one-inch diameter round copper pipe or tubing.

A good supplier of flat copper strap in various lengths and widths is Georgia Copper :

http://www.gacopper.com/012-CopperStrap.html

You want the copper strip to be several times the thickness of skin depth at the operating frequency. Skin depth at 40 meters is about 1 mil so a 12 mils thick copper strip will work fine on all amateur frequencies above 160 meters.

Dan

"Anyone know what the exact conversion from strip to tube diameter would be though?"

Te equivalent radio for strip to tube diameter is:

Req = (a + b) / 2

where

a: strip width
b: strip height

Best regards

Subject: Re: [loopantennas] Re: Soldered vs unsoldered joints

Dan,
I cannot find exact conversion from copper strip to copper tubing but the general rule of thumb for antenna builders is one-half the width of copper strip is equivalent to a round copper tube. So a two-inch wide strip of copper is about the same RF Resistance as a one-inch diameter round copper pipe or tubing.

A good supplier of flat copper strap in various lengths and widths is Georgia Copper :

http://www.gacopper.com/012-CopperStrap.html

You want the copper strip to be several times the thickness of skin depth at the operating frequency. Skin depth at 40 meters is about 1 mil so a 12 mils thick copper strip will work fine on all amateur frequencies above 160 meters.

Subject: [loopantennas] Re: Soldered vs unsoldered joints

If we are talking about resistance, I'm not sure it is that simple. The skin effect should behave differently on a flat strip than on a round tube. I think the tube will be a better geometry, but the strip will likely be thinner and so not as subject to the skin effect, depending on the frequency vs. the thickness. How thick is a copper strip? Or, how long is a piece of string?

As to the loop inductance, I don't think that will be significantly different from a pipe. In fact, the first formulas for inductance assume the coils are infinitely flat strips of conductor with infinitely narrow gaps between windings, hence the terms "sheet" inductance. All of the current flows in a sheet describing the coil. They have to make messy adjustments to the formulas to compensate for the geometry of "real" wires and tubing.

Is this really a practical approach? How many times can a copper sheet be bent before it creases and cracks?

How about 1/2" copper pipe?? you can sweat solder more critical areas (elbows, tees, misc fittings) together and still use the couplers to push together the loose ends using cotter pins or screws to hold the assembly together while in the air. I have used a battery post terminal cleaner to clean the inner and outer surfaces prior to soldering and such a device can be used prior to assembling the loop in the field. A side benefit is that copper pipe has less bulk than PVC and can be assembled and disassembled multiple times without worry about tearing. The detriment is that you are rather fixed to the possible geometries that can be fashioned but if square, rectangle, or octagon are possible forms, then this can be tried.

9662. Optimal load impedance

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-01-29 19:27:07 UTC
From: ALEX
Topic: 9662 Message: 9662

I am trying to find out what the optimal load impedance for a small untuned loop or dipole is, but I could not find a definitive answer so far.

A simple equivalent circuit of a small antenna consists of a voltage source V, a resistance R_rad + R_loss + R_load, and a reactance j*X. This applies to both a small loop and a short dipole, even the values of the elements of this circuit are of the same order of magnitude for both antenna types, the only difference between a dipole and a loop is the sign of the reactance. It follows from this circuit that the maximum power is transferred from the antenna to the load when

R_load = SQRT((R_rad + R_loss)^2 + |X|^2)

Since (R_rad + R_loss) << X, the optimal R_load is approximately |X|, a value in the range of hundreds of Ohms for both a dipole and a loop.

Nevertheless, some sources [1],[2] suggest that the input impedance of an amplifier connected to a small loop must be as low as possible, other sources [3] report success with a small loop and a common collector amplifier (the input impedance is hundreds of Ohms), and finally it is recommended to use a short dipole with a high input impedance amplifier [4]. Why so? Can anyone explain the discrepancy between the theory and practical recommendations? The loss of the received signal power could be huge due to the load impedance mismatch, nevertheless the recommended values vary by 6 orders of magnitude!

You are not necessarily trying to transfer maximum power and hence conjugate matching may not be appropriate. (it provides 50% loss, after all)

Also remember that for a small loop, the induced voltage increases with frequency since it's a function of dB/dt where B is the magnetic field. Hence you have a 6 dB / octave rising characteristic for induced voltage. If the loop operates into a low Z amplifier, the voltage divider formed by the loop inductive reactance and the the amplifier input impedance have a -6 dB/octave response that cancels the rising response. Hence you can have a flat response in terms of incident field versus loop amplifier output.

I'm from the electric power industry and getting a low resistance connection to aluminum conductors is a challenge. To splice two consuctions that might be an inch in diameter, there is a long tube that is slipped over both ends and the full length is crimped several time to get a good mechanical and electical contact with a lot of surface area in contact. If you had bolted copper conductors you would have to have a lot of surface area in contact under high pressure and also sealed with some kind of conductive coating between the bolted connections so that corrosion would not set in. Its easier to just have soldered connections with a lot of surface contact area.

My question is, where are you going to find a variable capacitor that has low enough resistance on its contacts even when it is soldered?

Hi Gene, thanks for your insights into some of the problems of trying to get a low-resistance connection between two pieces of metal without soldering or brazing.

Most people don't seem to understand that a low-resistance connection is very hard to achieve using bolt-on or clamp-on connections. That is why it is always recommended to solder all joints and connections in a copper transmitting loop. The radiation resistance of a transmitting loop is usually measured in milliohms, not ohms, so even a few milliohms of resistance in a joint can destroy the efficiency of a transmitting loop antenna.

For example if someone used even only a few inches of #12 wire to connect a variable capacitor to a loop, there would actually be more RF resistance in that short length of #12 wire than in the whole loop element. One rule of thumb that helps me is : if it doesn't look heavy enough to start a car with, forget it. No one would expect to be able to start a car with a piece of #12 wire. The wire would turn smoking hot, which is what I have seen with an actual transmitting loop running 100 watts of power when I tried to use a short piece of #12 wire for a connection to a capacitor. The current in a transmitting loop can approach 100 amperes or more running amateur power levels.

The best article I have seen on building a truly low-resistance variable capacitor for a transmitting loop is called "A Homebrew Loop Tuning Capacitor" by Bill Jones, KD7S. This article was in the November 1994 issue of QST magazine. A pdf copy is available for download free if you are an ARRL member.

The article describes building a "Trombone style" variable capacitor using part of the transmitting loop as one section of the capacitor and a U-Shaped section of copper tubing that slides in and out of the tubing ends of the transmitting loop using a motor and threaded rod for slow smooth tuning. The elements of the

capacitor are insulated from each other using high-quality Teflon or similar
plastic sheet rolled up over the inner set of tubing. Teflon sheet is one of the best
insulators known and will withstand much higher voltages than trying to use air-spacing
of the capacitor elements. The article has clear drawings and a clear explanation of how
it works.

I have built several successful transmitting loops using his design.

9666. Varactor tuned loop questions

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-01-30 15:18:46 UTC
From: Steve
Topic: 9666 Message: 9666

Hi folks - new to the group!

I'm thinking of building the varactor tuned loop from Christ Trask's paper "A Simple Varactor-Tuned Loop Antenna Matching Network" in the Files section.

I have a couple of questions:

1) Is there any reason not to use a couple of 1SV149 diodes in place of the MVAM109s? The 1SV149s seem to be more readily available!

2) Is there any need to take special precautions if the loop is positioned say, 20ft, from a Tx antenna at a power level of 400W?

Thanks,
Steve

9667. Re: [loopantennas] Varactor tuned loop questions

From: Richard (Rick) Karlquist
Topic: 9666 Message: 9667

You might also want to consider the "NCJ loop antenna" in the files section. It is even "simpler" (1 transformer vs 3 transformers, and it is inherently decoupled from the feed line.) Also available at this URL:

http://www.n6rk.com/loopantennas/NCJ_loop_antenna_N6RK.pdf

I recently worked VK6 and CE1 on 160 meters listening with this loop, and they were Q5 copy without a preamp on my FT1000.

Where are 1SV149's "readily available"? They should work fine AFAIK.

A loop 20 feet from a TX antenna, when not transmitting, is likely to have a very poor pattern due to the proximity of the TX antenna unless you go to a lot of trouble to detune it during RX.
When transmitting, you have to worry about blowing up your receiver from all the RF that will be picked up.

(snip)

Now I feel bad for buying 10 MVAM109s, off ebay, just because they were cheap, not because I needed them for anything. How many do you need?

Hi,

I am experimenting with receiving loops since last fall to be used on my business trips. Therefore the loops shall be transportable and immune to noise if used indoors or on the balcony. I built the varactor matching circuit by Chris Trask, but it did not fulfill the expectations. The matching was good at 80m, reasonable at 40m, but marginal at 30m and outright poor at 20m.

I am going to try the matching circuit described by N6RK. I measured two transformers wound with 5t:50t on a FT50-61 Amidon core yesterday, connected back to back at the high impedance side. The losses are 0.2dB per single transformer from 40m to 20m. At 80m, the transformer has a little bit low impedance, but as N6RK comments in his article, the impedance is absorbed by the loop tank. Above 20m, the losses are growing, but still very respectable for a receiving circuit.

Actually the losses of the Amidon 61 ferrite material are so low, that I am considering using it for a QRP transmitting loop. I guess a bit bigger core than size 50 has to be used, not because of heating, but because of high voltage strain.

Alex,

> Since (R_rad + R_loss) << X, the optimal R_load is approximately |X|, a value in the range of hundreds of Ohms for both a dipole and a loop.

Both small loop antenna and small dipole antenna, if built efficiently are of very high Q. That means a narrow band matching circuit in case of efficient power transfer.

> Nevertheless, some sources [1],[2] suggest that the input impedance of an amplifier connected to a small loop must be as low as possible

If the loading impedance is high, the loop starts acting as a dipole, which distorts the figure eight vertical radiation pattern and decreases immunity to a near E-field.

> other sources [3] report success with a small loop and a common collector amplifier (the input impedance is hundreds of Ohms),

Depends on what do you want to optimize. I recommend reading the following article from Chevdar LZ1AQ (thanks, Chevdar):
http://www.lz1aq.signacor.com/docs/wsml/wideband-active-sm-loop-antenna.htm
I recommmend to read all his technical articles anyway. It is a great source of technical and theoretic information on loops.

Basically, the higher the load impedance, the better the SNR, but the higher the lower frequency threshold, worse radiation diagram and more sensitive to E-field. The null depths and low sensitivity to E-field are the reason to install the loop antenna in city environment, therefore keeping the load resistance low is important.

> and finally it is recommended to use a short dipole with a high
input impedance amplifier [4].

That is a completely different kind of animal altogether. Chevdar's active antenna amplifier could be switched to magnetic or electric field mode. He comments, that in the E-field mode the antenna has a better SNR in a rural environment, but is more sensitive to close e-field noise than the mag loop mode.

> The loss of the received signal power could be huge due to the load impedance mismatch.

Chevdar compares SNR of a tuned loop against an untuned loop. The SNR of a tuned loop is better indeed because of conjugate matching. The noise of a tuned loop is mainly caused by the thermal noise of the loop resistance. The noise of an untuned loop caused mainly by the thermal noise of the load resistance.

No reason why not, but your tuning bandwidth will be different than that of the original design.

>
>2) Is there any need to take special precautions if the loop is positioned say, 20ft, from a Tx antenna
> at a power level of 400W?

I would suggest adding an SPST relay across the first transformer on the varactor side, closing the contacts when transmitting. That much power at that distance could possibly damage the varactors.

Chris

My thanks to everyone who responded"

As a footnote, a packet of 1SV149s arrived today, they and appear to be working fine. I have implemented Chris' idea of a relay for protection - it is driven from my station T/R line.

Thanks again.
Steve

9677. MFJ Hi Q Loop (MFJ-1786)

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-02-01 11:26:20 UTC
From: the_dalcassian
Topic: 9677 Message: 9677

I have just put up (Temp) my MFJ Hi Q Loop antenna at 6m above the ground mounted Horizontally polarised. I am having great RX/TX with this Antenna. I intend to permanently fix it at 12M above the ground Horizontally polarised.

I would like advise on extending the centr Aluminium pole by 300mm to take a 6M/2m/70cm Vertical Antenna, has anyone done this, will it detrimentally affect the swr on the Hi Q loop. perhaps I could extend by a Plastic pole then add the VHF vertical????

Any ideas on this proposal

Kind Regards Rodger (G8HLH).

I was thinking with regard to the NTE equivalent. This price is amazing. Didn't think that we would ever see affordable varactors of this range in a leaded package ever again. Certainly glad that this discussion came up as I can now look at other designs and not cringe at the cost of the varactors.

@ Chris,

Slightly OT, but I thought I might also try your loop amplifier in a wideband design! I'm struggling to find the MPS6521; would the BC550C be a suitable replacement?

Also, I see no value for C18 in the schematic, but two figures given for C15; I presume C18 is the 47uF and C15 100nF?

Thanks,
Steve

9680. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-02-02 03:57:01 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 9680

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

9682. Tuned loop better than untuned? How to match, what amplifier to use?

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-02-03 10:20:30 UTC
From: Vojtech
Topic: 9682 Message: 9682

Hello.

I studied the theory and experiments collected by Chavdar LZ1AQ carefuly. Chavdar concluded, that for a loop with diameter smaller tham 1m, the loading resistor of the transimpedance amplifier produces higher thermal noise than a background noise at higher HF HAM bands at quiet locations. He compared his untuned loop with a tuned loop of the same size at rural location experimentally and concluded that the tuned loop provides clearly better signal over noise. An untuned loop has a clear operating advantage, but in theory the tuned loop may be frequency calibrated and tuned in response to a transceiver frequency output at a CAT interface the same way the automatic band switching of transceiver accessories works.

I wonder whether matching a resonated loop with a balanced JFET high impedance source follower is a good design choice as there is a rumor that such an amplifier is prone to electric imbalance of the loop, which makes the loop act as an active monopole. Rick K6RK in his paper "An Improved Feed Network for Loop-Type Receiving Antennas" describes high impedance matching of a resonated loop by a transformer on an Amidon ferrite material 61 toroidal core. I measured two of these transformers back to back and the losses are very low indeed, which makes me thinking of using a W7IUV 20dB preamp just after the transformer to bring the loop signal power up to the normal levels. Is it a good idea, or will the JFET source follower work better?

Chavdar LZ1AQ loop experiments:

My experience with the NCJ loop is that no preamp is needed beyond the built in preamp in the radio. The loop as described in NCJ has more noise output than the noise floor of my Yaesu FT1000. The matching network described transforms ohmic losses in the coax to 50 ohms at the output connector. The effective noise temperature is therefore room temperature (300K). If you want to use a preamp, it can just be a conventional 50 ohm amplifier, where it is easy to get a NF of a few dB. Alternately, you can double the size of the loop and pick up about 9 dB, but it will now be 160 meters only.

Bring "the loop signal power up to the normal levels" will not increase the sensitivity if the external noise already is dominating. It will make the AGC perform better. My QTH is only 6 miles from a 50 kW BCB station, so I avoid preamps, and if I do use them, I have to preceed them by a high pass BCB reject filter.

Yes, very much so. The equivalent-diameter cylindrical-cross-section conductor corresponding to a flat, rectangular-cross-section conductor cannot be computed simply by taking the diameter of the cylinder formed by rolling the flat conductor into a tube.

I wrote a lengthy post on this subject for another forum. See here for details on how to compute the equivalent-tubing-diameter of flat conductors:
http://www.eham.net/ehamforum/smf/index.php/topic,86102.msg630653.html#msg630653

The brief summary is to read and understand everything W9CF has written on the subject, then use his approximations to compute an equivalent-resistance diameter and an equivalent-inductance diameter, and use those values to compute the small loop efficiency (explained in the above link).

I am doing an exercise in simplicity. Currently the only HAM HF transceiver in house is a tiny kit fitted in the Altoids tin - the ATS-3b by KD1JV. The receiver is a common 2x SA612 based superhetodyne. I matched a 37cm diameter loop wound with 1cm diameter aluminium tube to 50 Ohm coax using a transformer wound with 50t:3t on FT50-61 toroid core. The matching was verified with a VNA, matched impedance is around 40 Ohm on 40m, 80 Ohm on 20m, those are my primary bands of interest. Because the original band pass filters of the radio kit are lossy, I fitted the radio with a replacement bandpass filter with single resonated transformer wound on a FT37-6 core, matching the input 50 Ohm to the 1.5 kOhm input impedance of the SA612. This is my 2nd prototype, the first matching circuit just connected the loop to the input of the SA612 with a 4:1 Guanella transformer wound on FT50-43. The 4:1 matching provides a bit stronger signal, but I am sticking to the solution with the 50 Ohm coax and the 2nd resonator to ease the strain on the SA612. Yes, I know the theory sais the Guanella transformer will be lossy at high impedances because the transmission line impedance is low, but it works quite well in my situation.

I am doing this exercise as a learning oportunity and to have a portable receiving equipment for hotel stays. The loop has to fit into my backpack and has to be small enough to be easy to rotate and to fit on the window sill. The loop with the simple matching circuit to the SA612 performs reasonably at the outskirt of Prague, where the power line noise is very strong. I am able to significantly reduce the powerline noise by positioning the loop parallel to the powerline direction. The loop noise over receiver noise on 40m is quite marginal though and I will have to do more tests in the radio quite environment to asses whether the SA612 will provide enough amplification and be quiet enough to bring the background noise over the receiver noise. If not, then either an external amplifier or bigger loop will help, but I would rather avoid the 2nd.

My original question really was, what amplifier and amplification levels one really needs for such a tiny loop to overcome receiver noise (receiver without preamp) and whether it is better to amplify at low impedances or at the high impedances with the FET followers. I think I will have to try both.

To fit a bigger loop into a backpack means likely to build a wooden cross and using a coax for the loop, but then it would be difficult to rotate indoors and the symmetry will be compromised meaning worse chance to null out indoor noise.

With the 1 foot dmr loop on the windowsill with no preamp I hear NZ, US and JA stations on 40 and 20m regularly, so the loop certainly works.

9689. Capacitor for Carpet Loop Antenna

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-02-08 12:56:32 UTC
From: legitfromtheman
Topic: 9689 Message: 9689

Hello all,

I'm trying to buy all the parts needed to construct a carpet loop antenna as detailed:

http://f1.grp.yahoofs.com/v1/wOgUUWnH9vKjFDclXVfcy6nit1FVR-wxQXaamHyYZxkvnqIVpHFCsFuOnswa46vzcaDBqmU1tEPuuLknUeadDROTyh87MDtINq92Jf9B/carpetloop.pdf

The only part I cannot find is a 365pf variable capacitor. I can however find a variety of other capacitors, the easiest to source being one with a range of 0-200pf.

Can anyone tell me if a 200pf capacitor can be used for shortwave listening or do I need a capacitor as close to 365pF as possible? I am unsure what the different ranges on offer actually mean in reality. Does it equate to better fine tuning or would a smaller capacitor give a shorter tuning range?

Yahoogroups does those weird long links to prevent outsite sites from leeching bandwidth. So within 30 minutes of getting that link, it does not work.

The secret is to go to the File folder that the PDF is in, copy-paste that link: http://groups.yahoo.com/group/loopantennas/files/

Then append the name of the file: carpetloop.pdf

http://groups.yahoo.com/group/loopantennas/files/carpetloop.pdf

There are lots of them on eBay. Most old tube radios will have the type of capacitor you want. Look at the photo's on eBay to get an idea of what they look like.

Hello:)

What would work was to connect a say 75pf capacitor in parallel to the 200pf you have mentioned. Then you could even have a switch to use the extra 75 when needed. This would work for short wave listening no problems. You could even try copper tape around your skirting boards!

Good luck & 73

Hello.

I measured the maximum and minimum band noise of my 1ft dmr loop standing on a window sill. I am living near a HV power line and the attenuation of the powerline noise when turned towards the noise source is in the ballpark of -10dB (-13dB if I am optimistic). Is this a usual value, or shall I strive to do better?

Thanks, Vojtech OK1IAK

Dear Vojtech,

The null width of the loop is only a few degrees. Hence, as the noise source of the power-line is much wider than the loops null apperture then, is will be impossible to achieve a high null. Therefore a -10dB null is about right. Other factors that can affect the null is a lack of loop balance or poor isolation of the antenna to mains borne noise.

Kind regards

Andrew Ikin

Hi Vojtech: you must try at more distance from power lines. if u are living very close, you cant get a good null because the antenna is receiving noise transmited along the power line. the transmiter (power line) is not a puntual antenna and probably are receiving noise from angles different than the minimal rx .

You can also try and tilt the loop around the horizontal axis. This may give you few more dB. This is my actual observation.
Note that the orientation that gives maximum signal-to-noise is not necessary the same as the lowest noise, but it is usually pretty close.

Does anyone know where I can buy 30 feet of 660/46 Litz wire(solderable)?
It's available on ebay, but I would have to buy 60 feet or go outside of ebay to complete a transaction which I'm reluctant to do.

I want to build a two winding loop to plug into my existing rotateable loop antenna base so I can tune 1700 kHz to about 5,000 kHz.

Thanks. Bill Young WD5HOH

There is an ebay auction for 60 feet of 330/46 litz. You could parallel a pair of these to make your antenna, for $20.

Thanks. I did something like that years ago with some medical hardware and it worked. And, also I have an idea how I can solder Litz wire: I have a 100 Watt soldering iron with a broad tip. What if I melt a small "pool" of solder on the tip of the iron and push the cut end of the Litz wire into the molten solder and then tin it for say a half inch while it's being heated more or less uniformly by molten solder? There is an ebay auction for 60 feet of 330/46 litz. You could parallel a pair of these to make your antenna, for $20.

Did you use medical ecg patient cables? I wanted to use some for a very short length needed for an rf antenna connection. I stripped it back and found the very soft and fine wire. I'm figuring it Litz. I tried to find specs on the cables but no go. I have no idea what the impedance is.. I'm guessing its 50 ohms.

I can get a few of these easily.. They are usually 10 ft lengths. So for any decent length needed for a loop it'll have to be soldered together to get the needed length.

Is this what you did?

Thanks. I did something like that years ago with some medical hardware and it worked. And, also I have an idea how I can solder Litz wire: I have a 100 Watt soldering iron with a broad tip. What if I melt a small "pool" of solder on the tip of the iron and push the cut end of the Litz wire into the molten solder and then tin it for say a half inch while it's being heated more or less uniformly by molten solder? Phil, Some patient cables(at least this was true 30+ years ago) have graphite powder between the shield and the insulation around the center conductor. Some cable manufacturers claim the graphite reduces motion generated noise or "artifact". And the input impedance of a typical electrocardiogram(EKG or ECG) amplifier front end is no less than tens of megohms. And I won't guarantee that you can solder to the center conductor of a typical patient cable. Further I don't see why an EKG patient cable would be made with Litz wire. The EKG signal spectrum extends to a few thousand Hertz at most and the amplifier front end impedance is high. Skin effect is not a problem in that application. What I did years ago that's similar to what John suggested was to instruct a contractor to parallel another identical wire across an existing wire to get the impedance level between two points low enough to be within specification. Simple if you think about it but not immediately obvious. Bill Young WD5HOH To: loopantennas@yahoogroups.com

Guys,

If you are wanting to buy Litz wire, I have used this guy for the last 3 years, Ming, he does sell on eBay, but I have purchased wire directly from him about 8 to 10 times with good results. So if you want to go direct it is: _kwanmingmak@..._ (mailto:kwanmingmak@...)

I have bought well over 2,000' of his 660/46 and 330/46 Litz wire.

There is no problem soldering his wire, which is Chinese made. The way I solder it is to use a 40 watt iron, with good quality Rosen core solder and heat the wire while adding solder to the iron, which is placed under the wire. Once I have melted solder into the Litz wire I quickly wipe it with a rage and heat it up again and adding more solder and again wipe it.

When you heat the Litz wire you are melting/burning the varnish insulation on each wire strand, which leaves a lot of ash/cobs of black crap. I have soldered well over 200 to 300 Litz wire ends and have never broken one strand, that I know of.

I'm just becoming aware of Litz wire but only know limited info on it. I think it's having each strand insulated as a way of decreasing 'skin' effect? I'm sure there's a lot more to it than that.

Over the weekend I built a loop from a pdf I found somewhere that's from a UK mag 1989. This guy decided to make his own 'Litz' wire. He took 30awg wire-wrap wire, stuck a couple nails in his fence 100ft apart and ran the wire back and forth 16 times, chucked one end in a drill and wound it up. I didn't do that, I just used what I had, which was solid Cu enamled. I need to find something that's not so rigid.

Anyway, thoughts on what this guy did?

Reducing skin effect is most of it. It makes use of almost all the copper as part of the RF conductivity, without wasting the space (and surface capacitance) of having a large, effectively hollow conductor.

I like wire wrap wire, because it is silver plated and has a low loss insulation (Kynar) that puts the strands a lot farther apart than the enamelled strands of Litz, so the inductance per foot is lower (though the capacitance per foot is higher). But 30 ga. is way coarser than most Litz (down to 46 ga.) so it is really starting to have lots of skin effect at a MHz and above. But I think it is still a big improvement over solid wire, of the same overall cross section, even above the broadcast band.

A few years back, when I was crazy, I bought a huge reel (miles) of twisted pair, 30 ga, wire wrap (black and yellow) and have used only a few feet. If you or anyone wants a hunk of that to make into multi-strand rope, let me know by email, and I'll send you some.

Litz wire is not just twisted small gauge insulated wire. The gauge of the small strands is sized depending on the frequency range over which it will be used so that most of the wire cross section will carry RF current while minimizing skin effect. For example, for 850kHz. to 1.4MHz., 46 ga. wire is used. For 1kHz. to 10kHz., 30 ga. wire is used. This is because at lower frequencies the skin effect is less and larger sized wire can be used before skin effect starts occurring.

When they manufacture Litz wire it is wound in such a way that over any given length of cable, each wire strand will move through each possible position within the wire bundle. This is a much more complicated operation than just twisting the wires. With twisting any given strand will pretty much stay in the same position within the bundle relative to the other strands, while with Litz no two strands will stay near each for any length within the bundle as they are constantly changing position relative to each other.

Cheers,
John

Thanks John and John. I'm wondering whether I even need litz wire. Is one of the reasons for it to increase bandwidth?

Also, I think the Q on the antenna I just made is too high. It has a very sharp peak that's too narrow to pass the full station passband. I have a pdf regarding this and I can't locate it. I seem to recall that fewer turns results in more gain but less Q, and this is where I read that bit about being too sharp. Although, it said that this would be good for very crowded conditions, which I think might be helpful trying to get something from EU that might be between two stations here.

Something interesting I'm starting to think about, we picked up this qth a few years ago after someone else had gutted it and done a bunch of work on it. They re-sided it with cast plank siding, but underneath it they put a full sheath of foil covered insulation panels. Reception inside isn't too bad, the antenna does a fine job of nulling out the noise from the pellet stove, but I think I'm going to make my MW listening post on the third floor, which we had finished. The only thing up there is the roofing, with nothing inside except foam insulation and sheetrock. That'll be coming in the next week or so, I guess I'll find out if it makes much difference.

Thanks again,

Bill W2NVD

I would think a narrow BW means a high Q which means low
losses. Would an increased BW indicate higher losses? Are higher
losses preferred?

If a loop antenna is tuned with a capacitor it forms a tuned circuit. The Q of this circuit is the inductive reactance divided by the resistance. This tells you how large a voltage will form from a constant level of stimulus as the oscillations build up. A higher signal level of course is better at the input of the receiver. But it makes the circuit slower to respond to changes in the level of stimulus. This is manifested as a narrower bandwidth with a higher Q.

Think of a pendulum swinging. One with a heavier weight is like a circuit with a higher Q. It takes longer to get it swinging and once you stop pushing it, it takes longer to slow down. So it responds more slowly to changes and has a narrower bandwidth.

The tradeoff is between the signal level and the bandwidth. If you add more resistance to increase the bandwidth, you lower the signal level.

>
> But you can add as many turns as you wish to the primary to raise the primary inductance and lower the turns ratio.
>
> You can also tune the inductance with capacitance. This might work best with a series capacitor between the loop and the primary, and a parallel capacitance across the secondary of the transformer.

I've been doing some LTspice simulations on this. I think I need to add some passive circuitry to apply a DC bias to put the differential input on the edge of triggering, so I included this in the simulation along with the parasitic capacitance of the chip input. The antenna has a loop inductance of about 90 uH. In LTspice the transformer turns ratio is indicated by attaching the corresponding inductance on the secondary (L1*N^2). I'm not sure how a real transformer works in this regard, inductance of primary and secondary.

At very high turns ratios the parasitic capacitance creates a resonance with a null when looking at the tuning capacitance on the antenna. If that gets too close in frequency to the peak for the signal, it greatly disrupts the Q and the bandwidth making it very twitchy to tuning. Using the secondary capacitance alone to tune the response seems to drop the output voltage significantly with readings of -dB rather than some +60 to +70 dB when tuned with the primary capacitor. I'm not familiar with analysis of this circuit to understand why a null is created on the primary cap, but not the output...

The optimum balance seems to be a turns ratio around 25 to 33. In this range the difference in tuned output is in the 1 dB ballpark, but if the secondary capacitance drifts 1 pF the offtuning creates anywhere from -4 to -6 dB attenuation. Oddly at the higher turns ratios where the tuned signal is strongest the attenuation is such that the offtuned signal is weaker than at lower turns ratios. I'm not sure how realistic is a 1 pF drift with temperature, etc. of the inductor, PCB traces and the IC input.

Even odder is that if I add some capacitance to the secondary side in an attempt to swamp out the parasitic capacitance, the circuit has a higher Q and becomes *more* sensitive to that same 1 pF change!!!

I think I am a bit concerned with the capacitance of the secondary coil. If it has much capacitance I will have to run the coil with an even lower turns ratio.

No wonder they call it *complex* math.

Rick

Nice looking loop, but I'm not sure about using PVC as a former and cover is a good idea, Q wise.

From what I can ascertain, the loss tangent of PVC is around 0.023 at MW freqs.

You want to steer clear of PET ABS and PVC...

Table of loss tangents:
Polystyrene 0.0001 (recycle #6)
LDPE 0.00012 (recycle #4)
HDPE 0.0002 (recycle #2)
PTFE (Teflon) 0.00025
Polypropylene (PP) (recycle #5) 0.0002 - 0.0005
PET 0.014 (recycle #1)
ABS 0.02
PVC 0.023 (recycle #3)

Could you do some Q measurements on it, then try another one with polypropylene pipe instead? It would interesting to see if there is a major difference in Q factor.

I think one of the reasons the FSL's do so well is the construction technique - that foam stuff everyone uses between the ferrites and the coil has a nice low loss tangent.

If you upload your simulation file (not raw file), I will
take a look and check out your simulation, as best I can.

Maybe I'll be able to suggest some improvement.

But using a tube of plastic as a coil form is not making a
tuning capacitor with these plastics as the dielectric. It
is not even between the turns, but only beside them.

The plastic makes up only a fraction of the total dielectric
involved in the coil parallel capacitance.
So the plastic losses might not be so significant as these
numbers indicate.

Most crystal radio set builders have settled on Polystyrene
as the best material for highest-Q coil forms. Some crystal set
builders have built coils with Qs up to 2000 and above.

Once you get a good coil form material then the type of
wire used makes the biggest difference in Q with Litz Wire being
the best.

However receiving loop builders don't necessarily want the
highest Q as it will narrow the bandwidth too much making
the tuning very narrow and peaky and the audio sound narrow and muffled.

Some builders purposely use plain enameled wire instead
of Litz Wire for this reason. It will need to be trial and error
to find the best all-around Q without being too narrow.

But if you are going for all-out Q then try to use Polystyrene
for the coil form or supports and heavy Litz Wire like #660/46 for
broadcast band use.

Well Guys,

PVC would not be my first choice, however, it was the only thing that I could come up with that would work for my project. I know that Ben Tongue and the guys on Rap and Tap do not like PVC, but as Tod has mentioned those are the Crystal Radio gurus, where selectivity is very important.

All of that being said, Stormwise, whom sell their Monster Ferrite Rods, which are Ferrite slugs that are epoxied inside a thick walled PVC pipe and than there are the Brazilians whom have a lot of info on the web with their bundled Russian ferrite rods, which are housed inside of PVC pipe. So others are using it, even though it is not the best choice of materials.

I have no way to measure Q, however, I can say that the tuning is very sharp, which is an indication of high Q. I also saw very good rotational nulls, much better than my 1 meter air loop. What I did notice is that the tuning range was reduced from 400-2290 KHz to 400-2244 KHz, when I placed the 2" PVC pipe over the finished coil, so it did add a very minor amount of capacitance to the circuit.

I like the 660/46 Litz wire, even though it may have been over kill for this project, because it is easy to use, other than the soldering. It has about the same cross section area as 18 gage wire, but it is not springy, so the wire raps stay in place, it is like using a piece of string.

Based on my may experiments with different winding configurations I have found the Pollydoroff design, that I used in this project, to be a very good performer, over other configurations. However, in some of my earlier experiments I got some very strange results, like very wide tuning and sharp nulls on the high side of the station, but no nulls on the low side of the station. What I later found out was that you need a lot of space between the coils. I have had very good results with 1 1/2 to 3" of space between the coils. At some point I am going to try even wider spacing and I may try 6 coils. I have enough of the toroids to build a wider rod. The rule of thumb for the L/D ratio is 10:1 to 20:1, so I could go up to 28" on rod length, which should work well for a 6 coil Pollydoroff design loop.

That is a very good idea to wire in a variable resistor across the coil and some builders have done that in the past. It is called a "Q-Killer" resistor and it is a way to tailor the bandwidth of the loop antenna to your liking.

You can widen the bandwidth for best fidelity or narrow it down for best selectivity for DX and have the best of both worlds. I think something in the value of a 100K pot is used for this and a small switch to switch it in and out of the circuit.

Hi Tod,

I might give that a try with the new STLS, as the tuning is razor sharp and does somewhat distort the sound quality.

I should have a new play thing by the end of the week, as I ordered one of the new Commradio CR-1 Receivers. It will make it easer for me to evaluate my various antenna projects. It has a battery, so it should be very portable. _http://www.commradio.com/cr-1-communications-receiver/_ (http://www.commradio.com/cr-1-communications-receiver/)

Only the cost of using better materials than you need. You
can always lower the Q.

Use of a better plastic for the former/cover instead of PVC might allow for a loop with the same Q using normal wire instead of having to buy litz wire to make up for the dampening effect of the PVC.

Some PVC has lead added to it to make it last longer in sunlight IIRC.

I think that you are making too much to do about nothing when using PVC for a general use loop antenna. I have used PVC on several projects and it would be difficult to see any degraded performance from using it. As I mentioned before the only thing I have seen is a very small reduction in tuning range, which you can get from crossing the two wires going to the variable capacitor.

Build something and see for yourself, theory does not always prove out when applied in practice.

I built a 300mm diameter FSL with ferrites mounted inside the 10mm thick pvc pipe and the windings on the outside and the Q was terrible. Figuring out the Q problem is what lead me to loss tangents of plastics.

My current project uses 470mm diameter polypropylene with gapped ferrite rods. Unfortunately, completion has been delayed due to a tangental arduino-controlled stepper motor autotune variable capacitor project. Shouldn't be long now.

Give me more details, what kind of wire did you use, how many coils, if more than one coil, what spacing did you use between the coils?

A picture would be good also. You must have used a pipe coupling, with that thickness? The PVC that I used is less than 1 mm in thickness.

There are many things that can kill the Q and as you say it maybe the PVC, but it would be good to see what else is involved in the construction. Do you have any inductance info on the coil, number of turns and so on?

I've built a number of loops using copper tubing for the element proper and PVC for the support structure and haven't noticed any problems. But then I build mine a bit differently that other people do so as to simplify the construction and the method of tuning:

http://www.home.earthlink.net/~christrask/Paper012.html

There was some discussion about a year ago about the improved Q that results from separating the wires from the ferrite by way of a thin layer of plastic, such as PVC heat shrink tubing. It was a result of discussing the FSL.

I found this video of a jump rope twister, that shows the principles of twisting strands together, so they form a neat rope that does not unwind. I think the device is overly complicated and over priced. I made something very simple and cheap out of three bent cranks, made of hanger wire, that were turned, in unison, by a board with three holes.

"Red Hot Pepper Jump Rope Winder"
http://www.youtube.com/watch?v=yoFcY8qA4rw

http://www.wordworth.com/jump_rope.htm

I think the idea could easily be extended to 4 or 5 strands, not just 3.

I uploaded the simulation files to Antenna_LTspice.zip One is just the basic antenna circuit with the parasitic capacitance on the IC inputs. The other includes some circuitry I am adding to make the digital input work for low level AC signals.

I've done some more work with the simulation and I've also been doing some reading on tuned circuit and I think I understand it better. I can calculate the frequency of the various artifacts that I see now. To calculate the resonance peak, I need to reflect the secondary side capacitance to the primary side using the square of the turns ratio. Adding this to the primary capacitance and using that with the primary inductance gives me the frequency of resonance. The null in the primary cap (C1) voltage is just the resonance of the secondary side. When the frequency is reached where the parasitic cap (C2) resonates without the primary cap, the result is that the voltage on the L1 side of the transformer matches the exciting voltage and the C1 capacitor sees no voltage, so a null.

This is really a red herring and I was just confused by it. When this null gets close to the primary resonance, it means the secondary cap is getting very large and the primary cap is getting small. In the limit of using no primary cap the secondary cap will create a resonance but it won't have the advantage of the transformer turns ratio I expect and the resulting peak is not nearly as high as it could be. This limits the turns ratio to around 75 before the circuit becomes self resonant with the secondary parasitic capacitance.

I was seeing higher Q factors when I used a little secondary capacitance. But this doesn't really improve the signal strength at the output a lot. My real circuit has some passives to provide DC biasing so the digital input on the receiver will be most sensitive to the antenna signal. I included these components in the simulation file antenna.asc while antenna_transformer.asc only includes the transformer. These components were made high impedance, but still have some affect on the Q and max signal strength, limiting it to around 70 dB in the simulation.

In the end the best way to operate this circuit is with a turns ratio around 25 to 33 and with a minimum of capacitance on the secondary. This still produces a decent gain without the response being excessively peaky and overly sensitive to small changes in the secondary capacitance.

The coils I ended up with have 300 turns so I will be wrapping some number of turns on the primary to adjust the turns ratio. So that I can experiment with this, I expect to have multiple coils for the primary, 1, 2, 4 and 8 which will let me combine them in 15 combinations to produce turns ratios between 20 and 300.

My main concern is just how much variation I will see from temperature effects on the circuit once it has been tuned for 60,000 Hz. It may be very twitchy depending on how sensitive the parasitic capacitance is to temperature.

BTW, I've learned a lot about LTspice doing this design, not to mention tuned transformer circuits.

Rick

I took a look at your tuned transformer circuit and have altered it to illustrate a few concepts. I changed out the voltage source in the primary loop with a current fed, field coil, as a signal source. I also added an inductor in the primary loop to represent the antenna coil. The field coil is very loosely coupled to the antenna coil (K = 0.001), to represent the magnetic field the antenna will pick up from space, without the field generator coil having any significant effect on the tuning of the antenna inductor.

I also rearranged the current transformer, so that the secondary is a fixed inductance (as a prefab CT will have) and made the primary inductance a function of the primary turns count (that you will add).

I am working with a very clunky Windows simulator in a Linux system, so I did not have time to clean up everything and make sure all your measure commands still made sense. But I hope the concepts I introduced are clear enough to be useful for you.

I uploaded the file to the Popelish folder as Antenna_transformer_w_loop.asc

If I get the chance, I may work on it a bit more.

Let me know if this makes any sense to you.

I have wondered about the way I apply the stimulus. I think you misunderstand the circuit. L1 is the antenna coil. This is a large loop of wire which will make N turns around the coil core. I am unclear if the stimulus signal should be in series with the primary loop or if it should be applied across the cap and coil. In one case the primary will be a series resonant circuit in the other a parallel resonant circuit. The manner of stimulus is the only distinction that I can see between the two.

I'm not sure why the transformer should be changed the way you did. The antenna loop (L1) has a defined inductance. I actually had to research pretty hard to find a decent formula for it. Turns out there are *many* inductance formula and it is not so easy to figure out which one applies. How does the inductance of the two coils interact? I haven't found any good info on this. Most references assume both coils are wound in a similar way on a common core. I suppose the N turns around the core will affect the inductance of the primary. I don't have a number for the inductance of the secondary, the data sheet gives a very wide range, 180 - 335mH @1V, 10kHz.

I appreciate the time you are spending on this. One thing that still doesn't work perfectly is the center frequency measurement. It finds the max output value ok, but finding the frequency of that max value is not so easy. The method I use sometimes seems to "skip" over the match to the max value and gives an error. No information in the error message of course. LTspice is pretty great, but ease of use is not at the top of the list. BTW, they say LTspice runs great under wine. Have you tried that?

Just after I sent the prior message I was looking at the schematic and I get what you are doing with the separate coils in the primary. One is the antenna loop itself and the other is the turns around the secondary coil core. That makes sense. I'll play with this new configuration a bit.

Thanks,

Rick

There are probably several equivalent ways to put energy
into the antenna, but I like the field coil approach,
because I actually made a field coil to stimulate antennas.

The problem with your schematic is that the antenna coil
inductance is a separate inductive component than the
transformer primary, because one receives energy from the
external field and the other does not.

And the secondary inductance is not very high Q (it includes
significant core loss that shows up as something like a
parallel resistance across the secondary, because the high
permeability core is quite conductive). That is why the
entire system should not be tuned at the output of the
transformer. You don't want all the resonant stored energy
to have to slosh back and forth through that core. Most of
the inductive energy should be stored only in the high Q
antenna coil.

I tried, once, to install Wine, and hit a roadblock. My son is the Linux expert in the family, and one of these days, I want to try again, with his help.

One other point. There are two completely complementary ways to use a coupling transformer, in an attempt to increase the signal output of your loop. The transformer primary can be in series with both the loop and the tuning capacitor, when the primary inductance is low (relative to the loop inductance), or in parallel with both the loop inductor and tuning capacitor, when the primary inductance is high (relative to the loop inductance). If the turns ratio is not large, you might also find a small improvement by putting the secondary in series with the primary (correctly phased to have their voltages add), since you do not need electrical isolation from the transformer, That way, both windings contribute to the output voltage.

In your simulations, I think you should compare the possibilities for both these approaches with connecting your amplifier input directly across the parallel combination of loop and tuning capacitor.

One of the three might be a clear winner.

But is this core loss included in the simulation? I don't see a term for that anywhere.

Actually I get a higher Q by adding some capacitance to the secondary which increases the secondary currrent, but requires a lowering of the primary capacitance. I assume this is because the reduced primary current raises the Q of the primary circuit. So in the simulation I think the Q of the secondary is higher than the Q of the primary.

Some folks use a dual boot arrangement. Others run one OS and then run another in a sandbox under the first. I expect this takes a pretty good machine with lots of memory. Not something I have.

I worked on the measurement scripts a bit today. I am trying to measure all three features I see. I can calculate the frequency of the Vcap null exactly. That is the resonance of secondary inductance and capacitance. I can get within 5% of the first peak which is due to the total capacitance and the sum of the two inductors in the primary. But it is always low. I can't come up with any explanation of the higher frequency peak. No combination of inductance and capacitance in the circuit seems to produce this. I'm not comfortable not understanding what the simulation is telling me. That is rather the idea I think, to see

what it does and make sure it fits with the model. Otherwise the model may not be right. Obviously I don't understand the model.

I don't fully understand the field coil circuit. Why did you pick 1 mH for the radiator L4? I have no idea how to include that into the calculations and I don't know if this changes the signal strength value, not that it necessarily is a meaningful number anyway. But in my original circuit I assume the generator is the "untuned" voltage the antenna would receive and so the signal strength at Vout would be a realistic estimate of the level at the receiver input. I will try the other two methods of stimulating the circuit.

I also have some trouble getting LTspice to display "measured" data in meaningful ways. If it displays some data in dB, then *all* data is measured in dB. So if you want to see a straight numbmer it has to be reversed to anti-dB before being displayed. That is what some of my measurement statements were doing. lol

If you are interested I've uploaded a new file to your directory. Antenna_trans_LTspice.zip This contains the schematic with the radiator inductance set to match the antenna coil inductance along with the measurement file that can be run from the menu, File - Execute MEAS. Script. It is also in the schematic as commands, but the measure script can be run subsequent to the simulation.

I'm learning a few things about LTspice, but I still find the .MEAS command to be very cryptic.

Rick

9743. 100Ω -> 50Ω balun?

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-02-27 23:43:24 UTC
From: ceo@andygardner.com
Topic: 9743 Message: 9743

Greetings from sunny New Zealand,

My current loop antenna project has a variable capacitor and the stepper motor driving it in aluminium case at the antenna. As there are a number of wires required (for wires for stepper, 4 wires for optosensor limit detectors) I decided to use a DVI cable and connectors filched off old DVI video cards. I picked this because you can easily find high quality DVI cables lying around the house (well, my house anyway!) and they have 4 x 100Ω balanced individually foil shielded pairs along with extra wires. The good ones have ferrite chokes at each end of the cable too.

So I plan to have a pick up coil on the antenna that is 100Ω impedance to feed directly into the DVI cable, but when the cable gets to the other end (the controller box) I need a 100Ω-50Ω balun to feed the R8.

Looking for recommendations on the best balun design to use. Hoping to construct it using a toroid pilfered from old electronics gear - probably one that was used for interference suppression on a data cable run, rather than one used in a switch mode PSU.

Thanks in advance.

If you put a resistor across the secondary, you have a rough approximation of it. I think something in the decade of 1meg is close. You might also add a series resistance to that 300 turn secondary, since it is wound of pretty fine wire. Something about two times the specified DC resistance (to account for skin effect) might be about right. Of course, you can use the alternate Chan model of a core and get a lot closer for the distortion across the waveform, but that adds little to an AC analysis.

This is especially true if the transformer primary is connected in parallel to the loop and tuning capacitor (voltage transformer, rather than current transformer), since resonating the transformer will raise its overall impedance at the signal frequency.

I have a pretty spiffy machine. So I think it will handle Wine okay, once I get it installed, correctly.

The field coil inductance and driving current source are
completely arbitrary. They both function only as a signal
scale. It would probably be a good idea to pick a field
coil inductance and current so that a plain loop inductance,
possibly terminated with a meg ohm resistor or some such,
produced a 0db output at 60kHz. Then all other signal
strengths would be equivalent to gains.

I'll take a look. I have more problems with measure
commands than all other features of LTspice, put together.

I'm hoping for an expanded help section on this feature,
eventually.

I added a second loop inductor to the schematic, loaded only with 1meg and also coupled to both the field coil and the antenna coil by the same 0.001 K factor, and it looks like a field coil inductance of about 80mHy produces a 0db signal across that calibration inductor at 60 kHz. It also shows about a +-0.2 db signal swing as the antenna circuit passes through resonance, so this gives you an idea of how approximate the field coil is at representing a far field. Perhaps it would be a bit better to lower the K factor to 0.0001 and raise the field coil inductance to 800mHy. (a 0.02db coupling of the antenna back into the field coil.)

From: Andrew Ikin
Topic: 9747 Message: 9748

Lionel,

With two crossed loops you will also need a 90 degree combiner to achieve an omni-directional pattern. The problem here is, 90 degree combiners don't have a very wide bandwidth.

The other method is to use an SDR that has two antenna inputs and allows for the phase difference to be set at 90 degrees. This will also require a matched pair of loop antennas.

I have supplied ALA1530 loop antennas to some SDR manufactures for this purpose and for DF.

One other method is to build an up-conversion receiver with using 2 Mixers; each one uses the same LO but with a 90 degree phase difference. Both IFs are combined and down converted with another mixer and the same LO and then fed to the receiver. I guess the SDR method is easier!!!

Mount a single loop horizontally approx. 25ft above the ground to provide a near omni-directional pattern.

Lastly, do nothing, because HF signals tend to arrive at medium and high angles, where the loops pattern is omni-directional.

Almost. You'll need a 90 degree (quadrature) combiner to get the proper phasing for an omnidirectional pattern.

Topic: 9751 Message: 9752

Hello Yaakov

Nice collection of useful information . . One thing "I" would change is ===>
λ=40m F=07mHz R=.004Ω RL=.025Ω ΔW=04kHz X=046Ω E=14% Q=1600
λ=30m F=10mHz R=.017Ω RL=.029Ω ΔW=07kHz X=067Ω E=37% Q=1500
λ=20m F=14mHz R=.064Ω RL=.035Ω ΔW=15kHz X=092Ω E=65% Q=930
λ=15m F=21mHz R=.320Ω RL=.043Ω ΔW=50kHz X=140Ω E=89% Q=390

Is the use of "m" instead of "M" in the frequency list above. "M" for me implies mega and "m"
milli . . .

An addition to your list of helpful formulae might somehow include something about Path-Loss.
The one I use is PL = 22 + 20 * Log (# of wavelengths) . . . You can calculate this one "in your head" to a reasonable approximation . . .

I live in a CC&R location and will be fabricating a loop antenna soon. Your info should be very helpful.

Tnx and 73

9755. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-03-02 00:38:08 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 9755

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

9757. Question on MFJ - 1789 Loop Antenna for SWL

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-03-04 02:13:18 UTC
From: n2pkt
Topic: 9757 Message: 9757

I was thinking of purchasing the MFJ-1786 Loop Antenna to use for Shortwave Listening (in addition) to having it as my primary amateur radio antenna. I want to use it in my attic which is about 50 foot up on a high elevation. My present dipole grabs a lot of static from electrical sources. I thought this antenna would react similiar to Shortwave Magnetic Loop Antenna Pixel RF Pro 1B. Is this an option that I shoild explore? It is an expensive one, but I would not mind the investment if I could work DX as well as bring in weak stations on Shortwave "without" anymore static. I would appreciate any comments or suggestions! de Lou N2PKT

Lou,

Before spending the money on a commercial loop antenna I suggest you try making a tuned loop out of about 10' of coax and a dual section BC band variable cap. It may well prove to be an eye-opener to you. Tuned loops, contrary to popular misconception, are NOT inherently immune to electrical interference... they are just as prone to it as a dipole or random wire in the same environment. The main attraction to a tuned loop is its narrow bandwidth which acts like a sharply tuned preselector ahead of the rf stage of your receiver. Tuned loops are also strongly influenced by objects in their near vicinity (esp. within 1 to 2 loop diameters radius).

73,

'Bear' NH7SR

In my experience, the main advantage of any loop is the ability to NULL the interference by rotating the loop (and maybe also tilting it). Indeed, randomly placed loop outputs as much interference as a random wire.
Unfortunately, the desired orientation is band dependent, so a remotely controlled tuned loop requires two motors, one for tuning and one for rotation.

73, Mike

In the end, I took the lazy way out and decided to use an ethernet isolation transformer off a blown wireless router. Ethernet is 100Ω balanced, just like DVI, and one side has a centre tap earth.

Thank you both for your replies, If the Loop is still acceptable to static and other interference. I may look into better dipole systems
or maybe try the homebrew loop if I can locate some instructions.
For now, I will continue to look around for a better system. Thanks again! Lou N2PKT

I'm using http://www.mingtek.tw/pdf/B-4.pdf

100Ω balanced fed into pins 14 and 16

50Ω output to R8 from pin 1

pins 4 and 13 grounded

Feel free to tell me I got it all wrong, I would not be at all surprised.

Transformer (and balun) impedance ratios are proportional to the square of the turns ratios. Using only half of a winding reduces the impedance by a factor of 1/4.

In concept, since a 1:2 impedance ratio requires a turns ratio of 1:sqrt(2), that impedance ratio can be only approximated.

A turns ratio of 3:2 gives an impedance ratio of 9:4 or about 100:44.44.

A turns ratio of 4:3 gives an impedance ratio of 16:9 or about 100:56.25.

A turns ratio of 5:3 gives an impedance ratio of 25:9 or about 100:36.

A turns ratio of 5:4 gives an impedance ratio of 25:16 or about 100:64.

etc.

That coupled with the fact that the receiver probably doesn't have an exact 50 Ohm input Z, and of course the loop antenna Z is very likely to change over a fairly wide range anyway. So I sure wouldn't worry about some mismatch.

I have a similar setup here where I have an 88 Foot long dipole fed with ladder line (the best I can do here). It feeds an oversized 2KW 4:1 balun (oversized to minimize heating losses from changing the balun characteristics) before hitting the transmatch (MFJ949E). The balun is primarily there for balanced feed as I realize the impedance varies a great deal over the 3.5-29MHz range I use it. But it DOES perform very well on all HF bands (and I've even used it on 6M too). I've tried MANY different HF antennas in this Mobile home park (NO real estate space to speak of) and this one outperforms everything else I've tried.

Yes, some verticals were a bit better on DX (especially a Butternut HF2V I tried on 80/40), but their noise was WAY too high here.

So, I'd suggest just trying whatever matching ratio you have and see what works best for you overall.

After installing a 11 MB Chinese font file :-),
I find there are _five_ transfomer diagrams there
- you don't tell us which you use.

> > 100Ã□Â© balanced fed into pins 14 and 16
> > 50Ã□Â© output to R8 from pin 1
> > pins 4 and 13 grounded

Your pinouts only make any sense for two of them:
HN1664CG & HN1674CG. Let's hope it's the former.

> Transformer (and balun) impedance ratios are proportional to
> the square of the turns ratios. Using only half of a
> winding reduces the impedance by a factor of 1/4.

John has explained it well. A centre-tapped (usually
bi-filar) balun transformer is the way to connect an
FM dipole made of 300R twin feeder to the 75R coax
antenna input on the typical home hi-fi.

4:1 impedance ratio: half the voltage at 2x the current,
or 100R:25R. Also, if you are unlucky enough to have a
HN1674CG, you have the inductance of a half-connected
and un-specified current balun to add into the mix.

If you had access to all the transformer terminals
you could achieve a 3:2 or 4:3 turns ratio for one
of John's 'near miss' matches, but I imagine these
commodity transformers are inscrutably potted in
resin for their Ethernet isolation task.

However, does it matter for a receiver? There are
no damaging consequences of mismatch as in a Tx,
the coupling loop probably isn't 100R either, and
the only result might be transmission line
transformer effects when the cable gets to be
near an odd number of quarter wavelengths.

Better an antenna that works (mostly) than none.

Regards. LenW

I think you should compare the result you get with one of these Ethernet baluns with a home made unit made of 5 strands of something like 30 ga wire wrap wire, twisted together and wrapped a few times through a ferrite core.

Then you connect all those strands in series. The first 4 of them form the 100 ohm primary and the last 3 form the secondary. Two of those strands are part of both the primary and also part of the secondary. The end of strand 2 (which is the beginning of strand 3) is the ground point.

This arrangement gives you a 16:9 = 100:56 ohm balun.

Hi Lou,

I have purchased the MFJ 1786 & the Remote Controller (Necessary), I am delighted with it. Have worked the USA & Argentina on 5W at -20DB ... on JT65A. It is perfect for the digital modes as there is not much changing of frequency. I have mine at 15 foot above the ground (Outside) mounted horizontally. It will soon be at 35 feet mounted Horizontally in that polarization the nulls are vertical i.e. like wheel hub. That way I dont need a rotator. Anything of frequency by a small amount it does not pick up So it is very quite and pulls in anything I need when tuned. I suggest you keep a Dipole for general listening and then once decided just where to operate switch to the Mag Loop. Using the Digi modes as I do there is not so much jumping around as most of my contact are on spot frequencies. The MAG Loop is very selective and should significantly reduce your noise problem.

Kind Regards Rodger (G8HLH)

From: William Hein
Topic: 9757 Message: 9777

I recently moved to a new QTH and my "shack" here is mostly underground thus this superb directional low band rx antenna, which can sit on your rig or operating desk, is no longer suitable for my situation and is therefore for sale.

It is the latest and greatest version - the QUANTUM QX LOOP v2.0+ from Radio Plus Electronics - and includes plug in head units for three bands:

Long wave (160 - 530 kHz)
Medium wave (530 - 1700+ kHz)
Tropical band (1.8 - 6.2 MHz)

Easy to null QRM and peak weak signals by rotating or tilting the ferrite head unit which feeds a double balanced 40+ dB JFET/MOSFET preamp. Q-Multiplication allows super tight tuning. Runs on 9 - 15 VDC thru 2.5mm miniplug or 9 VDC battery.

More info:

http://www.dxtools.com/QXv2+.htm

Cost over $400 new and is still in EX condition. Will sell for $299 plus shipping via USPS, UPS or FedEx (your choice) or you pick up near Grand Junction CO.

Non-smoking shack. PayPal preferred but personal check OK with delay for clearance. Can send photo on request.

9778. New version of my Antenna Tuner project

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-03-19 02:48:58 UTC
From: pu2clr
Topic: 9778 Message: 9778

Hello everybody,

I would like to share the new version of my Antenna Tuner project.

Who liked the video "Magnetic Loop Antenna controlled by Arduino and infrared", will appreciate my last one.

Now I inserted an encoder to increase the possibilities to handle the antenna tuner. I also switch a Stepper Motor to a Servo.

To watch my video, access this link: http://youtu.be/zD-wKD19_8U

73.
PU2CLR,
Ricardo.

It just melts away as you solder. Keep your iron on longer than normal to burn aways the coating.

Make sure you heat it enough for all the little wires to get coated with the solder or the the Litz wire will not be as effective.

Steve,

The ACC connector has two pins which will help you - Pin 3 goes to ground on transmit and pin 8 supplies 13.8 volts at up to 1 amp.

Hang a coax changeover relay coil (12v, find on eBay or suplus dealer) between them to switch the two feeds to the 718's antenna socket.

An ordinary 12v power relay from any component supplier will do the job just as well if you want to build something yourself.

Don't build, just buy an MFJ-1707.

http://www.mfjenterprises.com/Product.php?productid=MFJ-1707

I used the similar MFJ-1708 for switching my antenna between the 718 used for transmit, and the Icom R75 for receive. Worked very reliably, never a problem.

The 1707 looks to be a nearly identical circuit, but switched one radio between antennas instead of the other way around.

9784. RF Sensing Circuit for use with Receive ONLY antennas

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-03-25 14:11:40 UTC
From: Bill McCourt - WF1L
Topic: 9784 Message: 9784

A ham in Indiana manufactures a series of boxes for use with beverage antennas some with amplification and others without but they have an rf sensing switch over circuit built into them to allow a receive only antenna to be used with a transceiver without a separate receive only antenna connection. I believe they're sold thru Radioworks and have his 9 call sign in the index tab.

I use one with my 160/80M receive only loop and it has the rf relay built in and works great! Have had it for several years now.

Good luck,

Bill - WF1L

9786. Various TOROID Winding Configurations

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-03-25 19:09:20 UTC
From: Garey Wittich
Topic: 9786 Message: 9786

There are various Toroid winding configurations - Bifilar, Overlapping, Autotransformer, Opposite-side.

How do you know which one is best to use ????

What are the Pros /Cons of the different winding configurations ?????

Many THANKS,

Garey Wittich Santa Monica, CA Palstar R30A + Windom Antenna

Subject: [loopantennas] RF Sensing Circuit for use with Receive ONLY antennas

A ham in Indiana manufactures a series of boxes for use with beverage antennas some with amplification and others without but they have an rf sensing switch over circuit built into them to allow a receive only antenna to be used with a transceiver without a separate receive only antenna connection. I believe they're sold thru Radioworks and have his 9 call sign in the index tab.

I use one with my 160/80M receive only loop and it has the rf relay built in and works great! Have had it for several years now.

Good luck,

Bill - WF1L

Circuit needed to switch IC-718 to receiving loop and then to trans

Sun Mar 24, 2013 8:48 am (PDT) . Posted by:

"p1jn3v11" p1jn3v11

I have a high noise problem due to high tension power transmission lines nearby. The IC-718 DSP noise filter does not do enough quieting.

I need a circuit that can allow the loop to be used on receive only

Thanks

Steve

Don't build, just buy an MFJ-1707.

http://www.mfjenterprises.com/Product.php?productid=MFJ-1707

I used the similar MFJ-1708 for switching my antenna between the 718 used for transmit, and the Icom R75 for receive. Worked very reliably, never a problem.

The 1707 looks to be a nearly identical circuit, but switched one radio between antennas instead of the other way around.

Subject: [loopantennas] Re: Circuit needed to switch IC-718 to receiving loop and then to transmit antenna

Steve,

The ACC connector has two pins which will help you - Pin 3 goes to ground on transmit and pin 8 supplies 13.8 volts at up to 1 amp.

Hang a coax changeover relay coil (12v, find on eBay or suplus dealer) between them to switch the two feeds to the 718's antenna socket.

An ordinary 12v power relay from any component supplier will do the job just as well if you want to build something yourself.

9793. QSO with my Magnetic Loop Antenna (QRP)

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-03-26 12:15:58 UTC
From: pu2clr
Topic: 9793 Message: 9793

Last week I posted a video on youtube about my home-brew Antenna Tuner - "Arduino, IR and Encoder controlling Magnetic Loop Antenna Tuner"

Yesterday I posted another video showing this system working (QSO with Magnetic Loop Antenna).

The first QSO is with EA2ACK, Jose, Cadrete (ZARAGOZA), Spain, 4964 mil (7990km) away from my city (Brasília/Brazil).

The second QSO is with PU5DUD, Renato, Blumenal, Santa Catarina, Brazil, 451 mil (727 km) away from Brasilia.

I used a FT817ND with 5 Watts.

I would like to share with you my last video on my Youtube channel.

The link to my youtube channel is:
https://www.youtube.com/user/pu2clr/videos?view=0&flow=grid

The link to my last video is: https://www.youtube.com/watch?v=ylhLfB0XhZU

The link about Antenna Tuner assembly is: https://www.youtube.com/watch?v=zD-wKD19_8U

You can also look for PU2CLR on Youtube web page.

9794. Automatic Antenna Tuner for QRP controlled by Android and Arduino

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-03-27 22:52:19 UTC
From: pu2clr
Topic: 9794 Message: 9794

Hello Everybody.

I would like to show you my homebrew Magnetic Loop Antenna working with a homebrew Antenna Tuner controlled by Android and Arduino.

Some times working with a Magnetic Loop Antenna can become uncomfortable because you have to tune the antenna every band or even frequency that you want to use.
In my antenna, I introduced a system that gives me the possibility to tune it remotely.

The main motivation to make a remote control for Magnetic Loop Antenna is to improve the performance tuning process.
I have observed that when we operate close to the antenna, in general, it affects the accuracy.

Operate away from the antenna decreases exposure to the electromagnetic field and also the risks with the high voltage of the capacitor.

In this project, I chose to control my antenna from a Mobile Phone with Android System. In addition, I introduced to the system, an SWR meter that enable an automatic tune. During the course of the capacitor of the antenna tuner, the Arduino saves the capacitor position and records the value of the SWR.
Once known the position of the capacitor which results in lowest SWR, the tuning is performed.

See my video about: Automatic Antenna Tuner for QRP controlled by Android and Arduino:
https://www.youtube.com/watch?v=cZjbZRGTyVc

Best Regards.
Ricardo.
PU2CLR.

9795. Re: [loopantennas] Velocity cable factor

Yahoo group: loopantennas (2013 — 2017)

From: Nestor Escala
Topic: 9792 Message: 9795

Hi Clement.

Your question is not clear.

Do you need a open-wire line with two lines H07V-K ? or other configurations?

The velocity factor is VP = 1/k, where k: dielectric constant, when the wave travel into the dielectric. For PVC k~ 3 to 6.

But also the VF = 1 / (c*(L*C)^0,5) where c is light velocity, L, inductance /meter and C: capacitance / meter. This is a VF for a transmission line. You need to know the configuration of the transmisission line for to know VF. In this case, the VF is strongly dependent of the capacitance. The capacitance is given by the dielectric: PVC-air-PVC in series for a paralell transmission line with H07V-K.

For rule of thumb, the VF for a wire open transmission line is ~ 0,90 / 0,989

Best regards

Nestor

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1. * Justice AM Loop Antenna (Active)
> - - - discontinued

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

9798. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-04-01 12:22:23 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 9798

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

9800. New Litz Loop Antenna

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-04-04 04:48:39 UTC
From: WilliamY
Topic: 9800 Message: 9800

For several months now I have been using a 3 foot by 5 foot two winding loop antenna wound with 28 AWG solid magnet wire with reasonably good results. There is a five turn tuned winding and a one turn output winding driving my Ten Tec RX320D receiver. These two windings are not separated by more than their insulating enamel. This antenna is situated east-west and does not rotate. I can receive WD2XSH/7 in Natchitoches, Louisiana frequently with a readable CW signal as well as a number of nondirectional beacons.

Now, however I have been designing an improved version to be wound with 100/44 litz wire. The two windings will be separated by about 7/16 inch. I have written a few lines of code in MS Small Basic to allow me to use an equation from F. E. Terman's 1943 Radio Engineering Handbook to related winding separation in inches to coupling coefficient k. I can then enter values of k in a circuit model in LTSPICE IV to optimize output to the receiver. The new antenna should have an 11 dB improvement in signal output and a calculated overall Q of 111. My present antenna described above has a calculated Q of 17.

Are these numbers likely to result in an audible improvement in antenna performance? Bill Young WD5HOH

9801. MFJ-Loop Tuner & 6M

Unless you are far from civilization, the performance of your receiving system is much more likely to be affected by the man-made interference levels than by your antenna efficiency. We are in a very different world compared to 1943.
In case there is one prevailing interference source, the antenna can help. But the parameter to look at is the null depth, and the antenna has to be rotated to minimize the noise .

Mike, No I live in a noisy suburban environment, and nulls don't help much here. I have a small 360 degrees rotatable loop for AM broadcast. The nulls are broad or non existent. Any loop I use here is surrounded by wiring in the walls and conducting objects including myself. My primary interest now is the new 472 kHz - 479 kHz amateur band, and I find that the CW setting on my RX320D makes enough signals audible to keep listening interesting. As for my use of an equation from a 1943 handbook I have noticed in this group some interest in optimizing the spacing between a tuned winding and the winding driving the receiver. I have just found a way to do that without "cut and try" that's all. I have yet to try one of the new ferrite core rotateable small loops. And they tilt for optimum azimuth also.That may be a whole new ball game. Bill Young WD5HOH

The J176 works; I've used both types in my homebrew Lankford amp.
They're both the same die geometry. Allelectronics.com, for one seller,
currently lists the J176.

One turn is just fine. It can be the same size as the main loop, or smaller, inside of the main loop.

That's because your receiver is much less sensitive to mismatched impedance than a transmitter.

FYI, Cat-5 cable also makes a good cheap transmission line. Either pair of the 4 pairs there is about 200 ohms balanced, two pairs paralleled is 100, all 4 pairs paralleled is about 50. Observe polarity at both ends.

I use it to carry component HDTV sigs around my house.

Good to above 100 MHz, IIRC.

What does a transmitter have to do with it? It is a receiving loop.

The impedance mismatch has no discernable effect. All three methods work well.

Shielded Loop
Antennas for the AM Band

Mar 8, 2013 5:01 PM, By
Doug Irwin CPBE DRB AMD

Last month I wrote some
about making a notch filter for the AM band. However, before you have any
signals to notch out, you must first, of course, have some signal to begin
with. Let's talk a little about shielded loop antennas for the AM (or MW) band.

If you have an AM station
in your group then it's quite likely that you'll need a clean off-air signal at
the studio location. That's not always as easy as it sounds at first; there
could be any number reasons that off-air reception is hampered or otherwise
less-than-perfect. And even if you don't have an AM station in your group there
are plenty of reasons you might need to receive one cleanly off-air: the
station you want to receive could be an EAS source, a news or sports source, or
maybe even a competitor. You could be relatively far away from them, or you
could be in a noisy environment (electrical noise that is) or perhaps there is
a strong local AM causing problems with reception of the weaker signal. A
shielded-loop antenna may very well be all you need to pull in a good signal.

Likely you already know
that the loop antenna is quite directional; it has its maximum reception
parallel to the plane of the loop, and nulls that are orthogonal to the loop
(that is, rotated 90 degrees). See Figure 1. The advantage to this is that, by
changing the bearing of the loop, you can optimize the desired to undesired
ratio as seen on its output. In other words, you might maximize the station you
want, hoping for a reduction in strength from the station you don't want; or
you might null out the station you don't want, while finding the one you do
still comes in OK.

When a loop is shielded
it means that the turns of the loop itself are inside of a shield -- one that
is open at some point. See Figure 2. This shielding has the very beneficial
effect of rejection of electrostatic fields -- often the source of noise
getting in to an AM receiver. Since the shield is open, the incident magnetic
fields (i.e., the station you want to receive) will still induce voltages in
the loop, thus providing a signal for your receiver.

There are quite a few
sources of this type of antenna. For starters, you could roll your own at the
very least as an experiment to see if your reception problems are solved. Take
a look at the engineer's notebook entry from Radio magazine at the link

below.

Years ago my friend John
Scherer used to build and sell shielded loop antennas; I mention his because he used to load the loop a little differently. Take a look at Figure 3. John made square loops from copper tubing, with PVC as the center insulator. The windings themselves were made from a ribbon cable. The number of turns of course depended upon where in the AM band the antenna was supposed to resonate. (If you want to hack this design yourself, take a look at this online calculator to figure out how much inductance the loop will have
http://www.technick.net/public/code/cp_dpage.php?aiocp_dp=util_inductance_rectangle

Then find the capacitor
that will in turn resonate the loop here: http://1728.org/resfreq.htm

A single-turn was coupled
to the main loop magnetically, and the main loop was resonated. That single turn drove a coax output that was meant to drive 50 ohms.

If you want to buy a
commercially made product, Belar Electronics makes a shielded loop antenna.

http://belar.com/AM/lp1.htm

This type of antenna is
also popular with ham radio operators and other hobbyists. Take a look at this one from AOR USA :
http://aorusa.com/antennas/la400.html. This one is not meant
to be used outside though, so hopefully it could find a safe place inside your radio station.

9813. Ferrite question

Hi to the group. I have an AM antenna ferrite that is broke. I've read some month ago on this group that it is possible to reglue without lack in performance. I've found in my junkbox a ferrite with the same diameter but longer than the original and it won't fit the available room of the radio. My question is: Should I reglue the original or replace with the longer one? How can I cut the second (longer) ferrite to the same length of the original? Thanks for any advice.
Danny

Given that the rod form is an open magnetic structure (there is already lots of air between the ends of the rod), there is almost no change in the effect of the rod, if it is broken and glued with minimal gap between the pieces. I suggest slow cure epoxy (stronger than the 5 minute cure stuff). But methacrylate (instant) glue works well, if you can get the pieces together right in a few seconds. Just don't use anything with mineral filler in it Anything opaque), because the particles in those add a larger gap between the pieces.

9815. stacking ferrite rods

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-04-13 09:51:26 UTC
From: Vojtech
Topic: 9815 Message: 9815

Hello.

I am experimenting with various receiving loop antennas for HAM bands up to 40m. I did try various single turn loops and they work well indeed, but they are a little too big to carry on a business trip.

I am now experimenting with ferrite rods. First experiment was done with a stacked RFI ferrite beads and it was a disaster. The Q at 80m was around 10. Then I stacked two unknown flat rods from my father's junk box side by side and the Q is now around 100 at 40m and the antenna made of four of the same rods making a square rod of 12mm x 17mm x 160mm produces marginal atmospheric noise over receiver noise when resonated and connected to a NE612 mixer input directly. I am living on the outskirt of Prague, the man made noise is relatively high.

I ordered 6 round ferrite NiZn rods 10mm dmr, 165mm long. The material has a permeability 200 compared to the Amidon 61 mix with permeability only 125. The Amidon 61 mix is usually recommended for the lower HAM bands. I am aware of the extended losses of my higher permeability material, but one cannot beat the price of the Czech made surplus material of the communist era, comparing $1.50 for the Czech rod to an unobtainable Amidon R61-050750 ($20-$25).

My question is: How to stack the rods? Some of the broadcast band rods are notched along the length of the rods. The ferrite material has some resistivity, therefore it sounds logical to insulate the rods from each other. Does it make a difference?

What ratio of diameter to length shall one maintain? What is the rule of thumb?

NiZn ferrite does not normally have a measurable resistance (when touched with a pair of ohm meter probes), so if you see a measurable resistance, I bet the rods are MgZn ferrite, and should be insulated from each other, if bundled.

Hi John.

You are right. I checked these rods with an ohm meter and I am unable to measure any resistance.

The performance of the rod is marginal on HF. If I only could find a source of a single aluminium replacement rim for a children bike. That would make a perfect high performance receiving loop for a traveler.

Loop Antenna News and Information ForumAs you're only interested in receiving, a large metal thing like a
bicycle rim isn't needed. The Sony loop (I think "LP-1" ??) uses
flexible steel wire that can be folded up small. However this
antenna is about $100 and even used ones fetch a good price.
I looked at some products here that use a similar flexible spring
wire. There are some "folding laundry baskets" for sale here
that use a similar wire. My thinking is to cut off all the synthetic
cloth material from this basket and remove one of the metal loops.
The amplifier could be built in a quite small plastics box with the
loop wire attached. I am thinking also use some kind of plastic
gripping clamp removed from something else; this clamp would
be moved onto the amplifier box, so the unit could be clamped
to a window frame or such.
I have also looked at something called "telephone C wire",
which is 2 flexible steel wires in a flexible plastics carrier,
used for the local "drop" from the pole to to the customer
house for wire telephone systems. This wire will self-support
and retain a circle form to a diameter of about 1/2 meter.

Hello Hue.

I would be careful using such a spring wire for a loop antenna. My 40cm dmr tuned loop made of 6mm aluminium tube provides band noise around 10-12dB on 40m band over the internal noise of a NE612 active mixer, which has a noise figure below 6dB. Using a good FET preamp one may gain likely additional 3dB of S/N. The S/N of a tuned loop depends mainly on the loop area and loop resistance accounting for a skin effect. Using a thin iron spring wire would seriously degrade the antenna S/N.

Talking about foldable laudry baskets. There are foldable shopping baskets with aluminium frame on the market. These baskets are quite pricey, but the aluminium frame is quite thick. One could bridge the joints with a copper braid. Aluminium is relatively easy soldered with a SnZn solder. The melting temperature of the SnZn solder is around 350 degree Celsius.

I'm building another shielded loop using a homebrew Burhan's preamp. This one will be either 9' or 10' in an octagonal shape. My previous shielded loops have always used RG-8 for the main element but this time I am considering RG-58 coax in an effort to reduce the wind loading a bit. I'm wondering if there would be any performance disadvantage by going to the smaller coax ?

Should work pretty much the same, though the bulk resistance will be a little higher due to the smaller cross section of the conductors.

Thanks Chris...that's kind of what I felt as well, the only real difference being the increased R but at this small size it would likely not be an issue....hopefully.

Hello All,

Has anyone had any experience with reducing a transmitting loop size by half by going to two turns? That seems to be a size that falls in between the usual definitions of a "small" narrow bandwidth loop, and the full wave, or "skywire" loop. I've not been able to find any info on the size, but it could make a rotatable loop for 40 meters at least within reason, at 15 or so feet square.

Cheers,

Brian Burns

Brian,
SGC TUNERS has something like that in one of their online PDF documents.
I think its in the "STEALTH BOOK".
I have it somewhere, if you cant find it.
It is on a PVC frame, four turns, I think.
With a SGC tuner they claim can tune up most hf bands.
I guess you could cut it exactly for 40. And no tuner.
I plan on building one for my attic, wishful thinking is 75 meters...:)
Vertical mounted, delta shape about 10x10x10. Multiple turns. Possibly on a rotor. R&D stage.
But then I can dream right;)

Hello again Mauro,

I had a look at the references that you sent, and it looks like these loops are definitely in the □small loop□ category.

I do like your home-made high voltage capacitor, and those are an impressive number of contacts for a compact antenna, and low power!

The antenna that I have in mind is in a kind of □no man□s land□ between the full wave, square loop with ¼ wavelength sides, and the narrow-band small loop.

I am fortunate to be able to put an antenna outside of my radio shack, but a square 40 meter full wave loop with 10 meter sides would be impractical. I□m just wondering if there would be much sacrifice in performance by going to a two turn loop with 1/8th wavelength (5 meter) sides, that resonates without a tuning capacitor, and has somewhat better bandwidth.

Thanks again for all the references! I love to see hams making their own gear out of materials from the hardware store!

Cheers,

Brian

Using more than 1 turn does nothing to increase the radiation efficiency of the loop, and may decrease it due to additional copper losses.

For a given size loop, the product of bandwidth and efficiency is bounded. Often, changes in loop design that increase that bandwidth decrease the efficiency. Using multiple turns does nothing to affect this inevitable tradeoff. For additional information, Google on "Wheeler Chu small antennas".

Thanks for the link to a good loop antenna article. I have been using the rectangular and square loop calculators at http://emclab.mst.edu/inductance/index.html for years. Very helpful. I wish I had room to make full use of the rotation and tilt features of the 3 or 4 foot box loop. Sharp, deep nulls would be useful. I have just completed a 42 inch by 58 inch rectangular loop with a five turn litz wire tuned winding and a one turn AWG #20 solid wire winding driving my ten Tec RX320D receiver. I have not found it worthwhile to leave space between turns, but the space between the windings is important. A relatively small distributed capacitance is not a problem for me, but I do like to maximize winding Q so I use "slot" windings, that is a winding with the wire pushed into a slot at each of the 4 cross arm ends. Keep in mind also that with litz wire you have to avoid sharp bends - I keep the bend radius for 100/44 litz at or above 1/4 inch. With a five turn slot winding and a one turn turn driver winding I can use LTSPICE IV to model the antenna performance. The model requires values for the coupling coefficient k which can be calculated using equations from F. E. Terman's Radio Engineers' Handbook, 1943. And this is much easier if each winding lies in one plane or nearly so. I have not been able to find anything more recent to relate k to winding separation. I find there is a functional relationship between k and antenna Q, so I maximize Q(hopefully improving the signal+noise/noise ratio thereby).My new 42 inch X 58 inch loop is located between a wooden bookcase and a wall(there is, I think house wiring inside that wall). My long range goal is to use this loop and my Ten Tec Rx320D to begin exploring WSPR-15 in the new 472 khz - 479 kHz amateur band. I live and operate in a noisy environment, but a good, high Q loop antenna will help. Thanks again for the article. Bill Young WD5HOH

Hello Rick,

Thanks for the reply, and the link!

~ Using more than 1 turn does nothing to increase the radiation efficiency of the loop, and may decrease it due to additional copper losses.

I'm expecting a decrease in radiation efficiency by going to a smaller size. I'm trying to avoid the very narrow bandwidth of the "small" loop, and the resultant need for a motor driven capacitor.

I can come up with a method of erecting a 5 meter (or so) square loop, and rotating it. If that size can be made to resonate on 40 meters by using two turns, without the need for additional capacitance, and can provide modest bandwidth and a bit of directional gain, then I'm happy.

The next fantasy is to turn that concept into a practical size of 40 meter cubical quad.

Cheers,

Brian__,,___

I don't know if this helps, but there is another Yahoogroup called "Skywires" (http://groups.yahoo.com/group/SkyWires/) which is more along the lines of full-size loops as opposed to small loops. I think what you're doing is closer to a full size loop ... just cutting the area in half but with about the same amount of wire. Thus, the observations about trying to increase the efficiency don't really apply. Small loops assume that the current is uniform around the circumference of the loop, which would not be true of your antenna.

I recall reading a question (in one of my many email lists over the last several years), by someone also considering a 2-turn loop. I don't recall now whether he was trying to make the loop area smaller (like you), or doubling the wire by wrapping it twice around the same footprint. In any event, my impression was that there was not a lot of work done in that area already and you, and he, might be on your own.

I have seen elsewhere that the "full size" loop supposedly can be used as low as where the loop is only a half wavelength long. Most references to full size loops say that the lowest frequency is 1 wavelength circumference; but apparently it can work at half that. (And I don't mean like the old QST Skywire article where they use an 80m loop on 160 by turning it into a top-loaded vertical!)

Andy

Here's something different in transmitting loop antennas that I found in an old ARRL Antenna Book with original reference cited in Electronics, January, 1963 - the DDRR (directional discontinuity ring radiator). It's basically a 1/4 wave radiator in a loop in close proximity to a ground plane/screen. It's main propagation mode is magnetic (loop is mounted horizontally, radiation is in the vertical plane ala NVIS). Feed to antenna is gamma type and loop is at ground potential. Diameter of tubing that comprises the loop varies according to frequency/band to minimize losses. A search using DDRR will turn up numerous references.

Hello Andy,

Thanks for the suggestions. I subscribed to "loop skywires" for quite a while, and may even have asked my two turn question there some time ago. You're right that there doesn't seem to have been much work on the idea, though Ike's suggestion looks promising. I really should shell out the cash to subscribe to AtennaX-I'll look into that.

Cheers,

Brian Burns

Rick,

What's to debunk about the DDRR? They work quite well when properly installed over a ground plane that extends to 2X the DDRR diameter. I installed a lot of them back in the '80s for use on VHF Lo-Band (30-50MHz) business radio systems. Nice fat, low angle pattern with a low profile and stable SWR when compared to a loaded whip. On VHF Hi-Band I used to install them as stealth antennas on the underside of unmarked police vehicles.

Don't knock it if you ain't tried it.

73,

'Bear' NH7SR

Because the originator's theory of operation ("directional discontinuity") is bunk.
It's just an inverted L with the horizontal wire bent into an arc.
Nothing new about bending the top of an inverted L, even in 1963.
With a very short vertical section (that's the only part that radiates). It doesn't make sense to limit yourself to such a short vertical unless you are under some sort of height limit. As far as working well is concerned, if high efficiency is somehow achieved in a DDRR, it is sure to have very limited bandwidth due to the small size. No way to get around that.

From: ik1wvq
Topic: 9845 Message: 9845

Hi to all,
there is a particular reason to place the coupling loop in the opposite side of the capacitor?
This is beacuse I am building a mono frequency mag loop for 28 MHz WSPR, and the capacitor (9pF FIXED) is a piece of RG8 coax cable without external braid slipped INSIDE the copper tube of the loop, and then is pratically invisible.
I would like (for mechanical reasons) to mount the loop with the capacitor at BOTTOM side, and put the coupling loop close to the "capacitor".

any contraindications?

thanks in advance for your attention..
best regards de Mauro IK1WVQ

Placing the coupling loop near the capacitor has the danger that you may unbalance the loop and cause common mode currents to flow on the coaxial cable shield, making the feedline part of the antenna. This can lead to increased noise on receive, and RF in the shack on transmit.

The loop voltage is highest near the capacitor. For example, in the following image I calculated the electric field around the capacitor for a 2 meter by 2 meter loop antenna resonant at 7 MHz:

http://postimg.org/image/n091ogqbl/

The capacitor is at the top of the loop. Notice that the electric field intensity around the capacitor is hundreds of times greater than that around the bottom of the loop. Therefore, if you attempt to place a coupling loop and the feedline near the capacitor, inside of this huge electric field, it becomes relatively easy to unbalance the loop which will cause common mode currents.

It is for this same reason that optimized small loops have the capacitor at the top: to keep everything (feedline, supporting structure, and ground) away from the massive electric field around the capacitor, in order to best preserve the loop balance and ensure that each opposite half of the loop is excited equally.

Is this a Sangean WR-2, with a coax antenna connector?

If so, there is probably a large impedance mismatch between
it and your (I assume) 4 turn, 1 foot loop.

Have you tried to tune the loop with a variable capacitor
(or some different fixed capacitor values)?

I think I would try connecting a tuning capacitor across the
4 turns, and connect the shell of the coax to the "ground"
(case) terminal of that capacitor, and one turn from that
node, to the pin of the coax connector.

Sorry, I looked at a photo that had only a coax (type F) antenna connector, but that is only for FM antennas. The one with optional AM antenna input has screw terminals.

But my idea for connecting across one turn of a multi-turn, tuned loop holds, but you connect that turn to the two screw terminals.

4nec2 (available free of charge). It's available here: http://www.qsl.net/4nec2/

For the near field, it can calculate and display in 3D the near E-field and near H-field. Note that in the above image, the horizontal purple line (very high voltage), extending far outside of the loop boundaries along the axis of the top side of the loop, may be some numeric calculation error, maybe due to the geometry or position of the loop. It doesn't make sense that the E-field would extend so far beyond the loop boundaries. (Maybe I should ask on the 4nec2 forum about this anomaly.) Apart from that, the results seem reasonable.

Here is the input file, if you want to experiment with the model. Save the following text to "something.nec" and load it into 4nec2. Note that the field separator, between items on a single line, is the tab character. The loop is resonant at 7.003 MHz, but has not been matched to 50 ohms.

9853. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-05-01 13:23:10 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 9853

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

As I understand it, the end of a transmitting loop with the tuning capacitor
is the high-impedance end of the loop. The opposite end is the low-impedance
or "cold" end of the loop.

The coupling loop is normally low impedance around 50 ohms so for best match
it should be located at the low impedance end of the loop and exactly opposite
the tuning capacitor for best loop balance.

It is too bad the best location for the coupling loop is opposite the
tuning capacitor as it would be more convenient to have the two close
together especially on a larger loop and for mechanical reasons.

Most builders place the coupling loop at the bottom end of the loop
near the ground, so the tuning capacitor should be placed at the highest
end of the loop, the hardest place to reach mechanically on a large
loop.

There is lots of room for experimenting with best coupling to a
transmitting loop so someone may come up with a better method
to couple near the tuning capacitor end and solve several problems at once.

From: heavenzgoat
Topic: 9857 Message: 9857

I found a discarded holder for TV dinner trays and thanks to this group I modified it to hold a box loop antenna, it's great because it has a nice handle on top to pick it up and turn it. Speaking of TV dinner, a non-functioning TV was the source for hundreds of feet of magnet wire and a burned up portable transistor radio provided the tuning cap so I'm into this for $0. Another roll of old twisted pair telephone cable and I could put the antenna across the house away from the computer equipment where my Sony home stereo receiver also sits. It doesn't have an internal ferrite, only two speaker-wire type spring terminals.

Here's my question, do you know the math on this? I'm listening to KFI Los Angeles 640 kHz 9:30 p.m. and I clearly in the background can hear WWV, which is on 2.5, 5, 10, 15 and 20 mHz, and also WWVB at 60 kHz. Is WWVB what I'm hearing and how do the radio harmonics work out where I can hear it? The time station fades in and out but it's very clear when it's there under Tim Conway's voice.

Thanks,
Vince

There is no voice on WWVB - it is totally in code. If you are hearing SW on your AMBC radio you've got a problem! 'course some old vintage radios were designed to work like this but not mixing signals from two bands on one. Did I say that right?

Are you SURE it's WWV? Do you hear, "At the tone, the time will be...", or are you just hearing ticks on the second? You didn't mention your location so I have no idea if this makes any sense, but could it be Radio Reloj out of Cuba? They do non-stop news in Spanish with ticks every second and "RR" in Morse code at the top of every minute. Might that be what you're hearing. Since you're getting KFI the Spanish might be very faint but the ticks and Morse code might pop through. Unless you live near the WWV transmitter and it's bleeding all over everything, I'm thinking Radio Reloj is more likely.

There is another way to couple into a loop antenna which is done at the tuning capacitor. It's known as the "army loop method tuner" since it was originally designed for use by the US Army. You can see it here...

http://homepage.ntlworld.com/g4kki.william/army_loop_tuner.htm

Might be worth a try.

This is one of those ideas I keep meaning to try. But then I keep thinking about the massive electrical field around the capacitor, and I just can't bring myself to place the loop controls, cables, and mounting structure near the capacitor where they risk upsetting the loop balance.

Here is a posting describing one user's problems with common mode currents when using the MFJ loop tuner, which is essentially the same as the army loop tuner linked above.

http://www.eham.net/ehamforum/smf/index.php?topic=87076.0

Note how WB6BYU states "such circuits are inherently unbalanced." So you can probably get the army loop tuner to work, but you may have to deal with common mode currents.

I'm along the Mex border between San Diego and Imperial counties. Even at a closer distance around 130 miles KFI still fades in and out and the time signal can be heard. I went back and very carefully listened to a recording I made a couple nights ago. I hear tones (not ticks) up to 15 seconds till and then ticks till the minute tone. Finally 12 minutes into the recording I heard the male WWV voice (it's hard to pick out with KFI being a talk station). So, it's clearly WWV, just trying to figure out what it's doing on 640 kHz, I haven't been able to find out anything from the receiver's user or service manuals (it's a Sony STR-K700). BTW I listen to KFI because the San Diego stations don't come in here at night.

Hi,
It wouldn't be3 the fact that WWV is on 640KCs, but rather images from the higher frequency SW stations being heard. Many (most) analog consumer grade receivers from years past had very poor front end selectivity and could pick up images in this way, especially if antennas other that the factory loop or loopstick are used, and there isn't a TRF (Tuned RF Amplifier) stage in the receiver.

What's occurring is that the shortwave station is blowing right past the front end of the receiver and mixing with harmonics of the local oscillator in the receiver. The LO of the typical analog receiver were often rich in harmonics and not as "clean" as the later PLL circuits of the more modern digital receivers.

It would be difficult to determine which of the WWV signals you are hearing as that would be dependent on the IF frequency of the receiver (probably 455KCs making the "first image" to be heard on the radio 1550KCs). But I would suspect that it's probably either the WWV 2.5 or 5 MCs signals as they would be strongest at night.

As a side point, when I was a kid in the late '50s I used to listen to shortwave on an "All American 5" (5 tube AC/DC) receiver by putting a longwire antenna on the "Mixer grid" (Loop antenna connection) of the tuning capacitor. It made for very tricky and fast tuning as the harmonics of the LO would tune faster than the main signal (if the LO were at 1600KCs and you tuned off by 1KCs, the 4th harmonic of the LO at 6400KCs would shift by 4KCs.

So, what is your answer? I would recommend more front end selectivity. That may be accomplished by building a small tunable pre-amp that tunes the BCB, between the antenna and the receiver. That should completely eliminate the problem,. I have two such circuits on my web site, designed for longwave they work well at BCB frequencies with appropriate coils.

See them here. . .

From: Jack Smith
Topic: 9857 Message: 9865

Looked at the service manual for the STR-K700 but the tuner is shown only as a block, ID TN1, with no details.

Some Japanese AM receivers use 450 KHz, not 455 KHz as the IF. If that is the case then ...

Tuned to 640 KHz, the local oscillator runs at 640 + 450 KHz = 1090 KHz.

5th harmonic of the LO is 5450 KHz. This is *exactly* the frequency to receive WWV at 5 MHz, as 5.450 MHz - 5.000 MHz = 450 KHz.

If the IF is at 455, the match fails. LO would be 1095 KHz and the 5th harmonic is 5475 KHz, so the difference frequency is then 5475 - 5000 = 475 KHz. That's far enough away from the 455 KHz IF that the normal selectivity in the 455 KHz IF chain will not pass the WWV mix without major attenuation.

So, my conjecture is:

(a) the tuner uses a 450 KHz IF
(b) 5th harmonic mix is occurring with WWV at 5 MHz.

The fix for it would be a low pass filter at the tuner input, cutoff frequency 2 MHz or so.

From the description you give, this is not WWVB, but may be one of the other WWV signals. From an article in 1971 "Broadcast Engineering",

"The WWV transmitters will remain at Fort Collins, Colorado, broadcasting on the same frequencies of 2.5, 5, 10, 15, 20, and 25 MHz. Power output will not change from the present 10 kW on 5, 10, 15, and 20 MHz and 2.5 kW on the other frequencies."

The article goes on to describe the ticks, tones and a once per minute voice announcement. So I would guess it is the 2.5 MHz signal since that is the closest in frequency, but I couldn't say why you are hearing this at 640 kHz. I assume the IF frequency is 455 kHz, no? So figure out what the LO is and do a little math to see how many harmonics up the scale it would have to be to mix WWV down. It doesn't look promising actually.

http://tf.nist.gov/timefreq/general/pdf/479.pdf

You can read more at wikipedia,

http://en.wikipedia.org/wiki/WWV_(radio_station)#Standard_frequency_signals

From: John
Topic: 9857 Message: 9868

Is your twisted pair telephone wire connected to a single turn of wire on your box loop and the variable capacitor connected only to the multiple turn 'loop'? If so, turning the capacitor should peak the KFI 640 kHz signal at some point, if the coil has something near the required inductance to resonate with the capacitor. I suspect you are using the telephone wire as a wire antenna - and possibly overloading the receiver's untuned front end at night, resulting in your local oscillator's harmonic content beating with WWV at 5 MHz (It works with a 450kHz Intermediate Frequency. With KFI 640 tuned, your local oscillator would be 450 kHz higher = 1,090 kHz. The fifth harmonic - 5,450 kHz - would beat against WWV at 5,000 kHz and pass through a 450 kHz IF. Some front end selectivity would help.).

You might go to AMAZON and look up 'AM Tunable Loop Antenna'. You'll find the Kaito/Grundig AN-200 for ~$25 with free s/h, if you 'try' Prime membership. 'Super Saver' free s/h works, too - for over $25. You can connect the loop to the twisted pair inputs - and tune it when you change frequency. Not as good as 'free' parts, but it works.

John

The tuned loop should provide enough selectivity.
I think the problem is the twisted pair. If it is connected just in parallel to the capacitor on the antenna end, it destroys the selectivity by loading the circuit with the capacitance and losses of its own. So John's first question is important. The proper way to connect the feedline to the loop is to tap at 1 turn. You will see that the peaking is much sharper in this case, and the SW signals are suppressed much better.
The pair itself also picks up signals from the air (unlike coax), bit it shouldn't be bad.

Yeah, that's definitely WWV. A little searching after posting that showed
Radio Reloj doesn't appear to broadcast on 640 kHz anyway.

I'm not all that far from you, but I've had great difficulty hearing WWV
even when I'm trying and on the right frequency. You must be in the prime
landing zone for one of the hops from the transmitter.

Hello,
New to the group but not to antenna modeling. I use EZNEC 5.0
One thing I have never figured out how to do is model a length of coax (as found in a "shielded" loop antenna. I know, it isn't really shielded . I scanned the posts and files areas but didn't find anything on the subject. If anyone has found a way to model coax I would sure like to hear about it.

This is exactly what I was looking for, I figured it had to do with the IF and some harmonic but I haven't wrapped my brain around the maths part of it! WWV on 5 mHz booms in here at night crystal clear, 2.5 not too good. This is a digital home stereo receiver with a great variety of inputs meant mainly for home theater and I'm sure AM radio is provided merely as a courtesy or afterthought. The included air core loop antenna is awful and meant only for local stations.

The box loop I made is closed, with a separate one turn around the box hooked to the twisted pair running across the open beam in the living room and into the computer/radio office. It's possible WWV at 5 mHz could be getting into that, it's a very strong signal here. Perhaps switching the feed line to coax would solve this. And like I said in another response, the AM radio part of this stereo system probably wasn't designed to have a nicer antenna than the nearly deaf one provided with the unit and I wouldn't be surprised that the front end is overwhelmed. Thanks for everyone's help, I consider the mystery solved!

If so, turning the capacitor should peak the KFI 640 kHz signal at some point, if the coil has something near the required inductance to resonate with the capacitor. I suspect you are using the telephone wire as a wire antenna - and possibly overloading the receiver's untuned front end at night, resulting in your local oscillator's harmonic content beating with WWV at 5 MHz (It works with a 450kHz Intermediate Frequency. With KFI 640 tuned, your local oscillator would be 450 kHz higher = 1,090 kHz. The fifth harmonic - 5,450 kHz - would beat against WWV at 5,000 kHz and pass through a 450 kHz IF. Some front end selectivity would help.).

I think you have got it. That radio is not really intended for DXing. It has too much antenna attached!

Just FYI: WWV doesn't transmit at 5 mHz. But you probably meant 5 MHz.

There's a world of difference between the two. Nine orders of magnitude, to be exact. Lots of people don't seem to realize that.

I have "similar" Sony receiver, the STR-D130. The AMBC is terrible except for very strong locals like KFI 640 with high power (50kW) or very close by. To properly hear local KABC 790 (7kW) I had to krank the volume way up to abut half way. So I stuffed a huge signal (IMHO) in from an outside active vertical antenna. Then wrapped 24ft of 20ga wire around that joke of a 4in x 4in plastic loop supplied to transfer the signal. Direct wiring and other methods including coupling loops, tunable loops I fooled around with didn't kut it. Still not good but a cleaner signal - yeah, no AMDX machines are these Sony's. I would not recommend these to anyone. I'm thinking of going back to my chinamart review and changing it.

A better solution that I was going to use was an outboard receiver like my Sony ICF 2010 and patch it into the front panel jack. Has manufacturing consumer electronics products really gotten this cheapo? You would think what used to be a good brand name like Sony with a cheap manufacturing base one could make a terrific or at least a passable radio for less, not just a terrible radio for less and lose any customer base they used have. Also I know not many apparently listen to AMBC anymore. Maybe that is what Sony thinks also?

Not a rant but a terrible section of an otherwise good product for the price point IMHO.

> This is exactly what I was looking for, I figured it had to do with the IF and some harmonic but I haven't wrapped my brain around the maths part of it! WWV on 5 mHz booms in here at night crystal clear, 2.5 not too good. This is a digital home stereo receiver with a great variety of inputs meant mainly for home theater and I'm sure AM radio is provided merely as a courtesy or afterthought. The included air core loop antenna is awful and meant only for local stations.

Thanks for the info about 4NEC2, I was able to run the file saved according to your directions.

A very informative page on voltages and current, electric and magnetic fields near a small loop can be read here:

http://www.w8ji.com/magnetic_receiving_loops.htm

regards,

JK

>
> For the near field, it can calculate and display in 3D the near E-field and near H-field. Note that in the above image, the horizontal purple line (very high voltage), extending far outside of the loop boundaries along the axis of the top side of the loop, may be some numeric calculation error, maybe due to the geometry or position of the loop. It doesn't make sense that the E-field would extend so far beyond the loop boundaries. (Maybe I should ask on the 4nec2 forum about this anomaly.) Apart from that, the results seem reasonable.
>
> Here is the input file, if you want to experiment with the model. Save the following text to "something.nec" and load it into 4nec2. Note that the field separator, between items on a single line, is the tab character. The loop is resonant at 7.003 MHz, but has not been matched to 50 ohms.

Loop Antenna News and Information ForumPerhaps the decline in AM receiver quality started with the single-chip receiver design.
I hadn't experienced directly any decline in Sony's AM quality, but I have not any real recent product of theirs. This week I picked up at a Goodwill thrift store a well-used Sony AM-FM portable for $4. Altho it looked less than great, I only wanted it for the variable cap and what I guessed would be a longer than usual ferrite bar. I mean longer than the nothings built into the ubiquitous small clock radios, those terrible things with digital clock and tiny slide rule dial radio. Anyway I thought I'd give this Sony a try before practicing the Aztec ritual on it. To my surprise, it had surprisingly good selectivity, the slide rule tuning was still smooth and the dial wide enough for very comfortable DXing. So this castoff radio will get to survive, after all.
Re the decline of AM band. Years back I took my car to the same name brand dealer's shop and along with other work, requested they look for the extreme noise disturbing the AM. The young work order writer declined to accept that work, and told me that they only got requests for attention to AM only rarely and that AM was only of interest to older people. In this coastal town of 8000, we have one AM station and 2 low power stations above 1600 kHz, one NOAA weather and one US Coast Guard local sea conditions broadcast. From talking to boaters I would have to guess that the number of people locally who know these special broadcasts exist, could be counted on one hand.
On the other hand.....yesterday we had a power outage of a couple hours due to a substation problem. We were stepping into a restaurant to see if they had anything left, and inside some people were discussing the power outage. I heard one tourist type say to the restaurant people, "When I heard the radio go off, I knew something was up." I was pleasantly surprised to hear this: apparently someone else listens to AM, too.

Complete STR-K700 service manual with schematics uploaded to the files.
Yes indeed the IF frequency is 450 KHz also the receiver is
sealed RF unit similar to TV unit.

I'm along the Mex border between San Diego and Imperial counties. Even at a closer distance around 130 miles KFI still fades in and out and the time signal can be heard. I went back and very carefully listened to a recording I made a couple nights ago. I hear tones (not ticks) up to 15 seconds till and then ticks till the minute tone. Finally 12 minutes into the recording I heard the male WWV voice (it's hard to pick out with KFI being a talk station). So, it's clearly WWV, just trying to figure out what it's doing on 640 kHz, I haven't been able to find out anything from the receiver's user or service manuals (it's a Sony STR-K700). BTW I listen to KFI because the San Diego stations don't come in here at night.

STR K700? That comes up as a 5.1 surround unit. Can you clarify the model?

Hi,
It wouldn't be3 the fact that WWV is on 640KCs, but rather images from the higher frequency SW stations being heard. Many (most) analog consumer grade receivers from years past had very poor front end selectivity and could pick up images in this way, especially if antennas other that the factory loop or loopstick are used, and there isn't a TRF (Tuned RF Amplifier) stage in the receiver.

  What's occurring is that the shortwave station is blowing right past the front end of the receiver and mixing with harmonics of the local oscillator in the receiver. The LO of the typical analog receiver were often rich in harmonics and not as "clean" as the later PLL circuits of the more modern digital receivers.

It would be difficult to determine which of the WWV signals you are hearing as that would be dependent on the IF frequency of the receiver (probably 455KCs making the "first image" to be heard on the radio 1550KCs). But I would suspect that it's probably either the WWV 2.5 or 5 MCs signals as they would be strongest at night.

As a side point, when I was a kid in the late '50s I used to listen to shortwave on an "All American 5" (5 tube AC/DC) receiver by putting a longwire antenna on the "Mixer grid" (Loop antenna connection) of the tuning capacitor. It made for very tricky and fast tuning as the harmonics of the LO would tune faster than the main signal (if the LO were at 1600KCs and you tuned off by 1KCs, the 4th harmonic of the LO at 6400KCs would shift by 4KCs.

So, what is your answer? I would recommend more front end selectivity. That may be accomplished by building a small tunable pre-amp that tunes the BCB, between the antenna and the receiver. That should completely eliminate the problem,. I have two such circuits on my web site, designed for longwave they work well at BCB frequencies with appropriate coils.

See them here. . .

I went back and very carefully listened to a recording I made a couple nights ago. I hear tones (not ticks) up to 15 seconds till and then ticks till the minute tone. Finally 12 minutes into the recording I heard the male WWV voice (it's hard to pick out with KFI being a talk station). So, it's clearly WWV, just trying to figure out what it's doing on 640 kHz, I haven't been able to find out anything from the receiver's user or service manuals (it's a Sony STR-K700). BTW I listen to KFI because the San Diego stations don't come in here at night.

    Posted by: "Jack Smith" Jack.Smith@cox.net k8zoa
    Date: Fri May 3, 2013 8:40 am ((PDT))

Looked at the service manual for the STR-K700 but the tuner is shown only as a block, ID TN1, with no details.

Some Japanese AM receivers use 450 KHz, not 455 KHz as the IF. If that is the case then ...

Tuned to 640 KHz, the local oscillator runs at 640 + 450 KHz = 1090 KHz.

5th harmonic of the LO is 5450 KHz. This is *exactly* the frequency to receive WWV at 5 MHz, as 5.450 MHz - 5.000 MHz = 450 KHz.

If the IF is at 455, the match fails. LO would be 1095 KHz and the 5th harmonic is 5475 KHz, so the difference frequency is then 5475 - 5000 = 475 KHz. That's far enough away from the 455 KHz IF that the normal selectivity in the 455 KHz IF chain will not pass the WWV mix without major attenuation.

So, my conjecture is:

(a) the tuner uses a 450 KHz IF
(b) 5th harmonic mix is occurring with WWV at 5 MHz.

The fix for it would be a low pass filter at the tuner input, cutoff frequency 2 MHz or so.

I guess there is a bunch of stuff out there on Loop antennas, theory and formula - and designing for a certain resonance.

I'd start here:
http://earmark.net/gesr/loop/

And there are these:
http://electronbunker.ca/Loop_Antennas.html
http://on2bbp.byze.be/projects/vlf-loop-antenna.php
http://www.frontiernet.net/~jadale/Loop.htm
http://www.vlf.it/octoloop/rlt-n4ywk.htm

1f. Re: WWVB question
    Posted by: "redsp" gnuarm.2006@... redsp
    Date: Fri May 3, 2013 8:51 am ((PDT))

From the description you give, this is not WWVB, but may be one of the other WWV signals. From an article in 1971 "Broadcast Engineering",

"The WWV transmitters will remain at Fort Collins, Colorado, broadcasting on the same frequencies of 2.5, 5, 10, 15, 20, and 25 MHz. Power output will not change from the present 10 kW on 5, 10, 15, and 20 MHz and 2.5 kW on the other frequencies."

The article goes on to describe the ticks, tones and a once per minute voice announcement. So I would guess it is the 2.5 MHz signal since that is the closest in frequency, but I couldn't say why you are hearing this at 640 kHz. I assume the IF frequency is 455 kHz, no? So figure out what the LO is and do a little math to see how many harmonics up the scale it would have to be to mix WWV down. It doesn't look promising actually.

http://tf.nist.gov/timefreq/general/pdf/479.pdf

You can read more at wikipedia,

http://en.wikipedia.org/wiki/WWV_(radio_station)#Standard_frequency_signals

Is your twisted pair telephone wire connected to a single turn of wire on your box loop and the variable capacitor connected only to the multiple turn 'loop'? If so, turning the capacitor should peak the KFI 640 kHz signal at some point, if the coil has something near the required inductance to resonate with the capacitor. I suspect you are using the telephone wire as a wire antenna - and possibly overloading the receiver's untuned front end at night, resulting in your local oscillator's harmonic content beating with WWV at 5 MHz (It works with a 450kHz Intermediate Frequency. With KFI 640 tuned, your local oscillator would be 450 kHz higher = 1,090 kHz. The fifth harmonic - 5,450 kHz - would beat against WWV at 5,000 kHz and pass through a 450 kHz IF. Some front end selectivity would help.).

You might go to AMAZON and look up 'AM Tunable Loop Antenna'. You'll find the Kaito/Grundig AN-200 for ~$25 with free s/h, if you 'try' Prime membership. 'Super Saver' free s/h works, too - for over $25. You can connect the loop to the twisted pair inputs - and tune it when you change frequency. Not as good as 'free' parts, but it works.

The tuned loop should provide enough selectivity.
I think the problem is the twisted pair. If it is connected just in parallel to the capacitor on the antenna end, it destroys the selectivity by loading the circuit with the capacitance and losses of its own. So John's first question is important. The proper way to connect the feedline to the loop is to tap at 1 turn. You will see that the peaking is much sharper in this case, and the SW signals are suppressed much better.
The pair itself also picks up signals from the air (unlike coax), bit it shouldn't be bad.

Yeah, that's definitely WWV. A little searching after posting that showed
Radio Reloj doesn't appear to broadcast on 640 kHz anyway.

I'm not all that far from you, but I've had great difficulty hearing WWV
even when I'm trying and on the right frequency. You must be in the prime
landing zone for one of the hops from the transmitter.

Hello,
New to the group but not to antenna modeling. I use EZNEC 5.0
One thing I have never figured out how to do is model a length of coax (as found in a
"shielded" loop antenna. I know, it isn't really shielded . I scanned the posts and files
areas but didn't find anything on the subject. If anyone has found a way to model coax I

would sure like to hear about it.

9885. RE: [loopantennas] CAT-5 cable?

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-05-13 17:42:57 UTC
From: Brian Burns
Topic: 9830 Message: 9885

Hello All,

My shack lends itself nicely to transmitting north and south with a dipole or vertical skywire loop, but the lot is way too narrow for stringing up such an antenna for east west work. It occurred to me that a simple full wave loop for 17 meters could be supported by a Dacron line at 43 feet that is already in place. Since a simple loop is bi-directional, there would only be the need to rotate it 90° to cover all directions, and it would have a db or two gain over a dipole.

So I looked up the full wave loop in the 1997 ARRL antenna handbook--downloaded for free from the AMforever forum, an excellent source for free downloads of back issues of magazines and handbooks. According to that handbook the nominal feed impedance of a full wave loop at resonance is 100 ohms.

That value sounded familiar, so I checked, and CAT-5 twisted pair cable has that impedance. I have a fond remembrance of the availability of 72 ohm balanced line, back in the day, and was wondering if anyone has tried feeding any sort of antenna with CAT-5 cable, or any other twisted pair configuration. Twisted pair supposedly picks up less noise and other signals, so it could well be a good receiving antenna transmission line.

CAT-5 may not have good weatherability for outdoor use, but that brings up the possibility of DIY twisted pair transmission line, and that really tickles my frugal Scottish whiskers!

Any thoughts or experiences on the subject would be appreciated (:->)

Cheers,

Brian Burns

Topic: 9830 Message: 9886

Hi,
I use a CAT6 cable to connect my "Active" longwave loop to the controller in the house. For my purposes it is ideal as I use one pair to feed power to the loop-amp, another pair to feed a variable Voltage from the "Tune" potentiometer in the controller to the Varactor tuning diodes, and finally, a pair to bring the signal back down into the house. In my case I use a BalUn at each end of the feedline to keep the line balanced, and RF chokes in each of the DC lines so that the loop is totally isolated from ground and noise on the DC lines.

It works very well for me, but of course, the highest frequency of the loop is 530KCs. Not sure how it would work on higher frequencies.

NOTE: There are different grades of CAT5 cable, some optimized for higher frequencies, (that's what I had). Without doing research (again) better stuff is called CAT6. . .

And yes, you CAN get UV resistant CAT cable, that's what I have, and it's grey colored. If in doubt, you can always spray paint it with a non-lead paint.

Brian,
I have used loop antennas both vertical and horizontal since
starting my SWL days in 1970.
Normally these have a been a full wave on 40m (138.5 ft) since the garden
can only take around 200ft perimeter and that is in ' no mans land '
coverage wise, the height has never exceeded 35ft.
All the loops have had the same feed system, an electrical 1/4 wave of 120 ohm
feeder (appx 23.5ft) which is no more than 15 amp rated black / red DC lead.
All fed from a Kenwood TS-130V with 5 watts SSB.. and to date 245 DXCC
entities worked / confirmed using 40 - 10m bands.
They do work despite the nickname of ' skywire ' hi!
A point to remember is that loops attract static and I have suffered a few ' belts '
over the years !!!!
Regards,
72, Brian, GØNSL.

When I needed to make up a set of long
"component" cables for my HDTV in the bedroom (to
reach from the DISH rx in the den), I looked up
the specs on CAT5 cable and found it to be a good
choice. I just put 3 rca plugs at each end and
marked them color-wise and plugged it all up.
Made an extra run for the stereo audio. Works
fine - no crosstalk, good freq response, etc. This was an 80 ft run.

The specs show extremely low crosstalk, and that
also means low/no pickup from external sources.

IIRC, the impedance for a single pair was 200
ohms, so two pairs paralleled would give 100 ohms
and all 4 pairs paralleled would give 50. I think
it would be an excellent feed line for up to maybe 100 watts RF.

Another commonly available balanced line in the 70-100 Ohm range is standard #18/#20 Zip cord - once known as lamp cord, but today known as speaker wire! Seriously - the vf was ~.66 back then - modern dielectrics may have changed that. Certainly there must be UV-tolerant variants now. Once upon a time, there was a company - maybe B&W - that made SWL receive-only trap dipoles that came either with the balanced Zip cord or a coax connector. For a receive feedline, it'll work well - if the dielectric is weatherproof. A lot of speaker cable is no longer pure copper - it's 'CCA' - Copper Clad Aluminum wire. Probably wouldn't do well flapping in the breeze - for long (Plastic failure of the Al core.).

I used it, years ago, to feed a homebrew Tilted Terminated Folded Dipole with, including a 2:1 (n ratio - Z ratio: 4:1) Z transformer (400 Ohm to ~100 Ohm) at the feedpoint insulator. It left the TTFD with no DC path to ground, so I went to 450 Ohm ladder line to a homebrew balanced tuner with a CT ground to drain off the static charge. Received signal strengths from common/stable SW stations, like CFRX, CHU, Radio Australia, WRNO, were similar in strength averaged over a few days. The TTFD is a great low noise antenna that pretty much loses the FD/Dipole bi-directional nature and seems more sensitive than it's signal dissipating resistor would imply. A 'loop' of sorts!

John

A few years ago, I measured the loss of typical zip cord, using lab grade equipment, taking due care to treat the line as balanced. Results:

The second column, "measured loss" is for a 17.4 ft length and the loss / 100 ft is extrapolated from that measured length. This is with matched loads - i.e., 109 ohms source and termination impedance (measured Zo for this piece of zip cord as 109 ohms). Operating it into a mis-matched load will, of course, increase the loss.

Frequency MHz Measured Loss (dB) Loss (dB)/100 ft
5 0.4 2.3
10 0.6 3.5
15 0.8 4.6
20 0.95 5.5
25 1.2 6.9
30 1.4 8.1

It's not the worst possible transmission line, I suppose, although it has greater loss than RG-174 (3.3 dB / 100 ft @ 10 MHz versus 3.5 dB/100 ft measured for the twin lead), it has the virtue of being available in an emergency from a hardware store. And, not all zip cord is equal. However, cables constructed to carry signals use rather different dielectric material than those constructed to carry 50/60 Hz power and that difference translates into significant loss.

At 10 MHz, CAT-5 ethernet cable has a loss of about 2 dB/100 ft, despite using significantly smaller diameter wire than for the measured zip cord.

So, will zip cord work as a transmission line? Yes. Does it work well? No, at least if one views the term "well" as including the concept of low loss.

Hello again All,

Thanks very much for all the responses on CAT-5!

A week ago a guitar making student of mine, who happens to be an EE, dumped a carload of "gems and junque" in my shop. Among the gems was a working 'scope, so I was happy to take on the disposal of the rest. Amongst what I thought of as junque was a 300 foot spool of standard RJ-11 telephone hook-up wire (several lifetime's supply). It's the 4 conductor standard stuff.

Until Jerry mentioned that CAT-5 would probably be useable up to 100 watts of RF, the possibility of using the RJ-11 wire as transmission line hadn't entered my head. There is a powerful incentive for using what you've got, if you have taken the vows of poverty, as I have.

I googled around for quite a while, but couldn't find any data on the characteristic impedance of the stuff, and was wondering if anyone happens to know anything about it. I would probably just parallel pairs of conductors to make a two conductor parallel line out of it.

Cheers,

Brian

I assume you mean the 4 conductor indoor (local premises) wiring cable - red, black, yellow and green. My Bell System friends called this JK cable if I remember correctly, but don't hold me to that.

It's also known, subsequently, as Cat-1 cable, and the normal recommendation is not to use it above a few hundred KHz.

On the other hand, there are umpteen miles of that wire still in use, and some of it is used with DSL which operates in the few MHz range at the upper end, so it will pass RF. The question is how well it will pass the RF as in a normal residential installation, the local premises wire will be only a few dozen feet in length and the overall circuit response is dominated by the distribution plant wiring, not the local premises wire. (Lots of equalization is used in the DSL modems to offset the high loss in telephone distribution plant once you up above audio range.)

The wire I'm thinking of is solid conductor, and probably would rapidly fail from metal fatigue if flexed by the wind. Also don't know if the jacket is UV stabilized of waterproof, as it's strictly an indoor use only cable.

As for impedance, I can't recall any specs on it, but I suspect from the dimensions it's in the 100 ohm range. Given the normal wire and insulation dimensions, it's difficult to make a cable the size of indoor telephone wire much outside the 100 ohm figure.

So, yes it can be made to work--wouldn't be my first choice but if that's the only way to transport RF, give it a try.

Hello Jack,

Thanks for the info!

~ I assume you mean the 4 conductor indoor (local premises) wiring cable - red, black, yellow and green.

Yep, that's it all right, but it happens to be stranded. Each conductor is made up of 7 strands of .006" diameter copper wire-I had to put on my 10X Optivisor to see the stuff!

~ On the other hand, there are umpteen miles of that wire still in use, and some of it is used with DSL which operates in the few MHz range at the upper end, so it will pass RF. The question is how well it will pass the RF.

~ Also don't know if the jacket is UV stabilized of waterproof, as it's strictly an indoor use only cable.

~ As for impedance, I can't recall any specs on it, but I suspect from the dimensions it's in the 100 ohm range. Given the normal wire and insulation dimensions, it's difficult to make a cable the size of indoor telephone wire much outside the 100 ohm figure.

The antenna will be located right outside my shack wall, and will be a PVC pipe that goes up vertically to support a couple of cross members that in turn support the loop. The phone cable could run up the interior of the PVC, and exit at the lower center of the loop so that it wouldn't be exposed to UV. The total length of the run would be about 30 feet.

I have a Harvey Wells antenna tuner that has a balanced output for open wire line, so it can match the transmitter to the phone line nicely. If the 100 ohm impedance of the line matches the 100 ohm impedance of the antenna, then "Bob's my uncle", right? I do love the idea of matching the impedances everywhere, even if it really doesn't matter very much (;->).

~ So, yes it can be made to work--wouldn't be my first choice but if that's the only way to transport RF, give it a try.

I could probably sell the spool of phone cable for enough to buy the "first choice", but there is something appealing about the idea of using the phone cable. BTW what would be your first choice?

Cheers,

Brian

First choice depends whether your design requires balanced or unbalanced feed line and the required impedance.

If high Z balanced, then 450 ohm ladder line, window type is reasonably low loss, mechanically decent and not terribly expensive. If you need low Z balanced line, there is a 72 or 75 ohm paired balanced line available, made with insulation designed for RF use. Some of these are available with copperweld conductors - that's fine if you need mechanical strength, but your description suggests a standard copper conductor version will be mechanically satisfactory. (Copperweld is miserable stuff to work with so I try to avoid it unless absolutely necessary.)

If unbalanced then there is a wealth of coaxial cables to consider. For a 30 ft run, it probably doesn't matter much, but RG-58 for small diameter coax or RG-213 for larger diameter would be it for me. Look for high quality cable, stay away from aluminum braid types unless you know exactly what you are doing. I would not buy cheap import coax cable unless you have the knowledge and experience to separate good from bad because a lot of it is really trash.

I've written a bit about coax cable:
http://www.cliftonlaboratories.com/the_curious_case_of.htm
http://www.cliftonlaboratories.com/Aug_2011.htm skip the first couple entries.

9895. Low impedance twin-lead

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-05-14 22:05:43 UTC
From: Brian Burns
Topic: 9895 Message: 9895

Hello Jack,

Thanks for all the references!

~ First choice depends whether your design requires balanced or unbalanced feed line and the required impedance.

Well a simple full wave loop is a balanced design, and if the '97 ARRL antenna handbook is to be believed, it has an impedance of 100 ohms at the feed point at resonance-hence my interest in low impedance, balanced feed-line.

So I got googling around to see if 75 ohm twin-lead is still available anywhere, and it is apparently "unobtanium". But I did run across this DIY suggestion on the AMfone forum in 2005:

"Get a spool of #20 or #22 teflon wire, and twist a couple twists per inch, and you will be quite close to 75 ohms."

This is just the sort of suggestion to tickle my whiskers. So, by varying the parameters a bit, it ought to be possible to make a twisted pair to whatever low impedance you might need.

On another forum I got told how little difference it makes to match the transmission line to the antenna as long as the transmitter is matched to the transmission line. But this is a hobby, right? And it looks like a fun, low cost research project to try making my own transmission line of just the right impedance.

Now, where do I get the cash for an MFJ 259B?

Cheers,

Brian Burns

It is easy to get CAT-5 cable, which has 100 ohm twisted pairs, and connect them in parallel to get 50, 33.3, or 25 ohms. It has low loss polyethylene dielectric, which makes it better than vinyl zipcord, especially as the frequency goes up. It is difficult to get much less than 50 ohms in a single twisted pair, even if you make your own out of thick wire with thin teflon insulation.

Hello Rick,

I found an on-line calculator for twisted pair parameters:

http://www.eeweb.com/toolbox/twisted-pair

~ It is easy to get CAT-5 cable, which has 100 ohm twisted pairs,
and connect them in parallel to get 50, 33.3, or 25 ohms.
It has low loss polyethylene dielectric, which makes it
better than vinyl zipcord, especially as the frequency
goes up. It is difficult to get much less than 50 ohms in
a single twisted pair, even if you make your own out of
thick wire with thin teflon insulation.

The impedances that I would be looking for are 72 ohms for a dipole and 100
ohms for a loop, so those should be practical values to come up with using
available wire. I'll run some numbers through the on-line calculator when I
get a chance.

I'm also curious about the supposedly low noise pickup by twisted pair for
receiving applications. Anybody have any experience along these lines?

Cheers,

Brian

It is possible to operate a transmission line with an intentional mismatch at the antenna.

The consequence of the mismatch is to increase the transmission line loss and peak voltage. If the transmission line is short, then the increased loss and higher peak voltage may be of little to no concern. Or, if the transmission line is very low loss, increased losses may not be important. The classic example is open wire line, spaced with ceramic or the like spreaders.

If you are using coaxial cable, then greater attention needs to be paid to the increased loss potential from a mismatch. In some cases it won't matter and in others it may be undesirable, depending on the degree of the mismatch, cable length, cable type, operating power and the like.

So if you were told that matching the antenna to the transmission line is not important, you were given greatly simplified information. Perhaps OK as a 0th order approximation, but not much more than that.

Yep,
Back in the day we twisted 300 ohm twin lead at 2 twists per foot to reduce noise and image pick up, course this was 55 to 60 years ago and YMMV.
We twisted long run speaker and unshielded cables on PA systems to help keep those rotten CB'ers out.

Hello Adrian,

I remember back in the day (1950's) that it was SOP to twist 300 ohm twin-lead for TV reception. This was in South Texas and the nearest TV station was in San Antonio. You think crummy programming is a current thing? Back then it was mostly wrestling, and a snowy picture.

Cheers,

Brian

I'm also curious about the supposedly low noise pickup by twisted pair for receiving applications. Anybody have any experience along these lines?

Brian
I remember when I moved to Phoenix in 1952 having only one channel and using rabbit ears? LOL
This was after living in Erie, PA with 6 stations to watch from USA & Canada, what a let down for a 6 year old.
Then in 1983 I married my 3rd wife (31 years next month) and her grandmother lived in Gila Bend AZ, using a Conical Ant and Twin lead over a 1000' mountain to get 2 out of 9 channels (3 and 5 snowy others clear but could fade) in Phoenix with no Cable in the area, took a lot of work over a year but I got her 7 of the 9 channels and a year later we put in Primestar for her.
She didn't know what to do with so many *clear* channels

Hello again Jack,

Well, the advice that I was being too picky about trying to match the transmission line to the antenna had mostly to do with low loss transmission lines like 600 ohm open wire line. I think that we all know that for all its virtues, coax at high SWR's can be significantly lossy, especially for long runs. But for me there is something aesthetic about matching impedances well. And the simplicity of twisted pair, and the possibility of making the stuff myself, really appeals.

To try to get at the principle of the thing on the other forum, I used a rather absurd example. I said imagine that I'm a QRP nut case looking for a new challenge. I've decided that I want to be the first ham to get Worked All States using my garage door opener. I need to get every microwatt from this transmitter delivered to the antenna. Now I'm really concerned about accurately matching the transmission line to the antenna as well as matching the transmitter to the transmission line, right? But nobody there seemed to be much amused, or wanted to think about it.

My principle in my work is to measure things as accurately as possible-you can always dial back from that if it's not going to make enough difference to make a difference

Cheers,

Brian

See my website: www.lessonsinlutherie.com

It is possible to operate a transmission line with an intentional mismatch at the antenna.

The consequence of the mismatch is to increase the transmission line loss and peak voltage. If the transmission line is short, then the increased loss and higher peak voltage may be of little to no concern. Or, if the transmission line is very low loss, increased losses may not be important. The classic example is open wire line, spaced with ceramic or the like spreaders.

If you are using coaxial cable, then greater attention needs to be paid to the increased loss potential from a mismatch. In some cases it won't matter and in others it may be undesirable, depending on the degree of the mismatch, cable length, cable type, operating power and the like.

So if you were told that matching the antenna to the transmission line is not important, you were given greatly simplified information. Perhaps OK as

a 0th order approximation, but not much more than that.

Matching impedances everywhere can help for a couple of reasons. One, for a given medium, the lower the SWR on that medium, the lower the loss. But be careful about that one, because if you change the medium (say by going from a mostly air dielectric to polyethylene or nylon), the losses change. And two, by matching impedances, you get better control over the final impedance your rig needs to drive.

Let's use an example. Say you have a 1-wavelength loop, and that your t-line is 3/4 of a wavelength long. The loop's feedpoint impedance on its fundamental resonance is somewhere near 100 ohms. Now let's say you feed it with 600 ohm balanced line. Sure the line losses don't matter (compared to coax) even with the 6:1 SWR on the line because it is low loss. But that length will transform the impedance, by going one and a half times around the Smith chart, to around 3600 ohms at the shack end. Either your rig needs to drive a 3600 ohm load, or a combination of antenna tuner and balun needs to bring 3600 ohms balanced down to 50 ohms unbalanced.

So by using 100 ohm balanced line, you end up with a terminal impedance that stays at 100 ohms at the shack end, which is easier to match. By being easier to match, it might also mean lower losses in your antenna tuner.

But on the other hand, the loss in your balanced line might be higher, because much of the medium is now plastic rather than air. It's just like the problem of using coax, maybe even worse.

And you might not want to use the loop on other bands with that balanced line, where the SWR on the line goes up, and with it, the loss. I'm not saying it is worse than the 600 ohm open line case, just saying it isn't a low-loss line simply because it is twinlead instead of coax.

So there are trade-offs no matter how you do it.

Andy

Another possibility for balanced, low impedance cable, is Cat-5 Ethernet cable. Each pair has an impedance of about 100 ohms, and if you parallel all 4 pairs the total impedance is a bit less than 25 ohms. The insulation on those wires has pretty low loss up to 100MHz and the 4 parallel conductors have a lot of surface area, for lower RF resistance.

This is a common misconception. The loss of CAT 5 twisted pair
is a few dB per 100 feet at 10 MHz IIRC from when I measured it.
Paralleling multiple twisted pairs does not change the loss at
all, even though there is more copper area. The reason why it
doesn't change the loss is that the increase in current due to
the lower Zo exactly cancels out the effect of the lowered resistance.

Sorry, If I missed your earlier post. I am away from home and trying to keep up with a web email reader.

I did not mean to imply that the loss would be lower for paralleled pairs than it would be for a single pair, if each were matched to a load. I was thinking of the earlier suggestion to twist a pair of 22 AWG enameled wires together, to make a low impedance line. I think the loss would be lower for paralleled pairs in CAT-5 than for that twisted pair (again, for a load matched to the line). But, I admit that I have not performed the measurement.

Yes, you are right that the loss would be lower with parallel CAT 5.
However, 22 AWG enameled twisted pair would not realize an impedance as
low as 25 ohms in the first place. I don't know any way to get 25
ohms with any twisted pair. If someone can tell me how to do that,
I would be interested.

As far as I can determine, Lefferson's 1971 paper on twisted wire transmission lines formed from magnet wire is primary source document. One of his concluding paragraphs states that the range of feasible line impedances ranges from 10 to 60 ohms for a single twisted pair.

However, from a quick review of his paper - and it really needs much more than a quick scan - no. 21 AWG twisted with a pitch angle of 45 degrees is around 25 ohms Zo. However, he also notes that 45 degrees is about the limiting factor for pitch angle, based on the mechanical strength of copper.

Somewhere, in the last year, I came across a webpage with good information about low impedance twisted pairs or parallel wires.

IIRC, it mentioned the previously-available low impedance ribbon cable, which has become hard to obtain.

He then performed a series of experiments, making his own lines out of wire. As I recall, he found it difficult if not impossible to get below 100 ohms by twisting ordinary insulated wire, because the insulation thickness was the limiting factor. It would require very fat wire with thin insulation, and even then, you get into some serious diminishing returns because the wire is round. (He didn't consider magnet wire.) He was able to achieve close to 50 ohms (or maybe he was aiming for 72 ohms, the theoretical feedpoint impedance of a resonant dipole) only by parallelling one insulated wire with one bare copper wire. It was not very practical, but it worked.

P. Lefferson, Twisted Magnet Wire Transmission Line, IEEE Transactions on Parts, Hybrids and Packaging, Vol. PHP-7, No. 4, December 1971, pp 148-154. There's also a correction at page 67 in a subsequent issue, but my copy doesn't have the correction citation, just the correction details.

Peter Lefferson is (or was, not sure if he's still alive) a ham, by the way.

Wish I could. Can't find that webpage article right now. I'm fairly sure I took a snapshot of it so I probably have it on the other computer's disk.

Apparently Belden made a 72 or 75 ohm twinlead half a century ago, and Amphenol had one with a P/N of 214-023.

I don't have the info available, but many years ago there was also a shielded pair cable called (I believe) "Twinax". I seem to recall that it was 75 Ohms, and at least some of the military radios (I'm thinking either the R-390 or SP-600) had a special balanced input antenna connector just for that cable. That might be a viable alternative if you can find any. . .

Many years have gone by and my memory isn't what it once was.

I am not sure that CAT-5 would be the best thing to use at RF. As one who has probed 100 Mbit Ethernet, I can tell you that the received waveform is severely attenuated and looks nothing like the transmitted waveform. All of the faster Ethernet speeds rely heavily on equalization to compensate for the cable rolloff.

Looking at some CAT-5 cable specs, I note that the DC resistance is on the order of 0.2 ohm per meter (not surprising for 24 AWG), and there is something about a 57 kHz corner frequency, perhaps either the -3 dB point or the skin depth frequency. That's kHz, not MHz.

Don't confuse CAT-5's "100 MHz" spec as an indication that it is flat or low-loss to 100 MHz. It definitely is not. It probably means the characteristics are repeatable to 100 MHz and that the loss at 100 MHz is workable given the current state-of-the-art in on-chip active equalization.

For experimental purposes and for fun, short lengths of CAT-5 might work; but I would not expect it to do well. And it can't handle much power; probably not a lot more than 10 W safely, per pair.

The JK (or JKT?) indoor phone wire I have seen, is four wires with a gentle twist of the whole bunch. Taking a cross section, the four wires are in a square. The "pairs", if you will, are opposite corners of the square. Thus, if the signals on both pairs are differential, crosstalk is minimized because even though each pair is fully immersed within the field of the other pair, it is in such a way that the differential components cancel.

The use of opposite corners to form a pair, raises the characteristic impedance from what it would be if they had twisted the pairs.

Since this stuff was intended for voice use only, they might have never characterized its impedance Zo. At audio frequencies, twisted pair copper wires do not have a constant characteristic impedance. It typically increases by more than an order of magnitude at audio frequencies, compared to higher frequencies where it finally levels off.

There is some mythology that telco uses Zo = 600 ohms for all its wire pairs. I have seen references that argue why this is not true. In the very very old days telco used open wire lines which might have been in that range, or greater. Twisted wire lines in cable bundles, which make up the majority of telco lines, were closer to 100 ohms Zo, but did not reach that until well above audio frequencies.

When I'm winding 12.5/50 Ohm 1:4 current baluns and need a winding Zo of 25 Ohms, I use a couple of lengths of RG316 wired in parallel (total power handling 2.5kW at 30MHz). An example at the bottom of this page:
http://www.karinya.net/g3txq/cobweb/

Strap them in series instead of parallel and you have a Zo of 100 Ohms for a 50/200 Ohm 4:1 balun.

I find that approach more straightforward than trying to fabricate a "pair" with the required 25 Ohm impedance and power handling.

According to the data published here (http://www.cerrowire.com/consumer-rg6u-coax), CAT-5 has lower insertion loss (attenuation) than inexpensive coax. For a 100' run of cable at 55 MHz, the published figures are:

RG-59 6.73 dB
RG-6U 5.25 dB
CAT-5 4.34 (interpolated).

The results of the actual measurements (http://www.ieee802.org/3/10GBT/public/mar03/cohen_1_0303.pdf) indicate that the nominal parameters of CAT-5 are worst case, the typical values are even better.

Subject: Re: [loopantennas] Low impedance twin-lead

I am not sure that CAT-5 would be the best thing to use at RF. As one who has probed 100 Mbit Ethernet, I can tell you that the received waveform is severely attenuated and looks nothing like the transmitted waveform. All of the faster Ethernet speeds rely heavily on equalization to compensate for the cable rolloff.

Looking at some CAT-5 cable specs, I note that the DC resistance is on the order of 0.2 ohm per meter (not surprising for 24 AWG), and there is something about a 57 kHz corner frequency, perhaps either the -3 dB point or the skin depth frequency. That's kHz, not MHz.

Don't confuse CAT-5's "100 MHz" spec as an indication that it is flat or low-loss to 100 MHz. It definitely is not. It probably means the characteristics are repeatable to 100 MHz and that the loss at 100 MHz is workable given the current state-of-the-art in on-chip active equalization.

For experimental purposes and for fun, short lengths of CAT-5 might work; but I would not expect it to do well. And it can't handle much power; probably not a lot more than 10 W safely, per pair.

Andy

I measured 2.3 dB per 100 ft. at 10 MHz. This is slightly higher
than the number above, if adjusted for SQRT(frequency).

The loss is very close to the theoretical open wire line loss
using the usual formula, at least at these "low" frequencies
where the effect of the wire twist is negligible.

If you wire the cable as the traditional "4-wire line" then it turns out that the characteristic impedance is 70.7% of the impedance of an individual side by side pair. 4 wire line ties together opposite wires and then drives the tied pairs against each other. This is normally described in the context of open wire line with circular disk spacers, but the concept should be extensible to quadrifilar twisted line.

Have you a reference for this 4 wire transmission line configuration and
impedance?
I can't find one. All I find is references to star-quad audio cable, that
is intended to be used this way, for low impedance mics. And it is
shielded.

Hi,

did anybody actually tried this back in 2005 or later? Are there any results? This thread is pretty old and seems to lack any conclusion :)

I was planning to try to do exactly this (variable dielectric capacitor) and found this thread while doing my research.

>
> it occurred to me that single sided copper clad board might be suitable for
> the capacitor plates as long as the substrate material was not interior to
> the capacitor plates and subject to the fields. i don't think it should
> contribute to loss in that postion.

Exactly my thinking, it might make one very cheap variable capacitor that can withstand both high voltage and high current.

My plan is to take two copper clad boards, separate them using plastic spacers (4 or 5mm) and slide polystyrene board between the copper planes.

According to the resources (links below) I found online, polystyrene has tangent loss of about 2 - 5 x 10^-4 and relative permitivity of about 2.5. That is actually not bad at all as Mica has "similar" loss properties.

http://www.rfcafe.com/references/electrical/dielectric-constants-strengths.htm
http://www.kayelaby.npl.co.uk/general_physics/2_6/2_6_5.html
http://www.eccosorb.eu/sites/default/files/files/dielectric-chart.pdf

Polystyrene also supposedly has much higher dielectric strength (197kV/cm) than air (10-30kV/cm) so arcing does not have to be an issue (especially for QRP or low power) as well.

9925. 50MHz reception using a modified Wellbrook 1530 Loop

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-05-16 14:49:59 UTC
From: Philip
Topic: 9925 Message: 9925

Hello all,

I have been a very keen VHF DX chaser for over 20 years, until a house move in 2009 stopped me having beam antennas.

When I ordered my Wellbrook ALA-1530 magnetic loop antenna I had enquired first about the 1530+ model which appeared to cover up to 100 MHz.

I found the 1530+ was no longer in production, but that it was possible for me to order a 1530 and choose not to have the VHF attenuators fitted, with a slight loss in HF performance on 18 & 21 MHz.

I was very pleased with my Wellbrook 1530 loop on HF over the past few months and now in May 2013 I have been able to compare it with my other antennas on the 50 MHz band. The results have been quite surprising!

My modified Wellbrook 1530 loop had consistantly outperformed both my 50 MHz vertical antenna and my 280' horizontal dipole when listening to 50 MHz signals via Sporadic-E. Signals are very much stronger on my loop from all over Europe and sometimes I cannot hear them at all on my other antennas which I have used for 50 MHz reception in recent years.

I am going to experiment with the loop for reception of Band 1 TV carriers via Meteor Scatter next.

My loop is at ground level too and no longer on a small mast.

I just wanted to share my results with you in case it is of interest.

Phil,

All ALA1530 loops built before 2010 would have a similar VHF responce as mentioned in your post.

The reason for the inclusion of the VHF filter was due to some North American users being concerned that the loop had too much gain in the FM band. The only satisfactory way I could reduce the VHF gain without degrading the upper HF performance was to move the loop/amplifier resonance from approx. 40MHz down to 14MHz by loading the loop with some capacitance. This also had the added benefit of increasing the amplifier input z above 14MHz and thus improve the loop/amplifier matching, to give a 5dB gain increase. Hence, the amplifier would provide a reasonable loop impedance track over a 1:20 ratio. Previously this had been approx. 1:12 ratio. The loop and amplifier input z is about 10-15 Ohms at 1MHz. With the present amplifier design, the transistor Miller capacitance limits the HF gain and input z. One option would be to use a cascode amplifier, this can provide 1:30 impedance tracking ratio. At the moment it is too early to say whether this option is worthwhile. However it may improve the lower VHF gain with loop loading caps removed!!!

No, I haven't tried a variable dielectric capacitor, but I have tried what I called a "floating rotor" variable capacitor with a metal plate rotating into and out of the space between two fixed capacitor plates. The resulting change in capacitance for 180 degrees of rotation is small but very useful for fine tuning a receiver. See QEX May/June 2002, page 31. Bill Young WD5HOH

Are you saying that the amplifier input impedance is a positive reactance that tracks the positive reactance of the loop? Or is it possibly a resistive input impedance that tracks the magnitude of the loop reactance? Is the amplifier connected directly to the loop feedpoint, or is there intervening coaxial line?

Should work. By theory a capacitor is nothing more than 2 opposite potential surfaces separated by a dielectric (air, fiberglass, some sort of plastic, etc). Using square plates will produce very non linear capacitance values as capacitance is affected by the area of the opposing plates. PITA to try to calculate, too! One thing to be aware with what you are planning is that you may have to account for air acting as a dielectric when you insert and remove the polystyrene between the two plates. May not be a large contribution to the overall capacitance but needs to be looked at. Not trying to talk you out of trying this. Let us know how it turns out!

>My plan is to take two copper clad boards, separate them using plastic
spacers (4 or 5mm) and slide polystyrene board between the copper planes.

I took a basic electricity course seemingly eons ago where we took two sheets of aluminum foil and slightly larger pieces of wax paper. The wax paper was inserted between the foil and the 2nd sheet was laid on top of the foil of what would be the inner surface of the capacitor. The entire assembly was rolled/folded up into a tubular capacitor type form and jumper wires were connected, one to each sheet of foil. The capacitor was then connected to a low current assembly with a known value resistor and an NE-2 neon bulb. We could then see the neon bulb flash at a rate corresponding to the value of the capacitors made by the class. Since this class was geared towards elementary school children, we did not try to calculate/approximate the dielectric value of wax paper, though in retrospect, it would be a good exercise for high school physics.

73

Rick N6RK

Rick, The amplifier input impedance is positive approx. +70 degrees over most design bandwidth and this tracks the loops rising positive reactance with frequency. The Amplifier connexion is directly to the loop.

If one looks the A F of the ALA1530 and a very low input z amplifier of Wellbrook LFL1010 using basically the same amplifier. The LFL1010 has a nearly constant A F of 15dB from 70kHz to 30MHz, whereas the A F of the ALA1530 at 70kHz is 21.0dB gradually rising to 0.5dB at 25MHz
On average the ALA1530 impedance tracking yields a 10dB increase in sensitivity from 500kHz to 30MHz.

Put it another way, very low input z amps. are okay from low sensitivity loops for say EMC work.

73

Andrew

P. S.

A F is the Antenna Factor in dB

Antenna Factor to receiver indication converts dBuV to dBuV/m

Receiver indication assumes the antenna driving into a 50 Ohm system.

For example, if the receiver indication at 300kHz was 90dBuV, the Field strength is 99dBuV/m. Hence, the A F would be 9dB

The lower the A.F. the more sensitive the antenna.

9933. Using CAT5

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-05-17 16:29:32 UTC
From: john
Topic: 9933 Message: 9933

Hi all. For those interested in the use of CAT5 cable, have a look at this site. http://www.lz1aq.signacor.com/

I have one of LZ1AQ'S loops here and it is now my most used recieving antenna. Highly recommended.

It is fed using 30m of CAT 5 with no problems. For outdoor use, CAT5 / 6 is available in forms suitable for this use - uses a rugged black external jacket rather than the flimsy blue stuff used for internal cable. The only issues may be sourcing it - try a wholesaler though buying a short length is probably hard to do as they usually sell by the drum. Another possible source is a data / comms installer who may be more likely to sell a short length especially if he has some scrap lengths tucked away. Otherwise just possibly spray paint the blue stuff some unobtrusive colour and accept that replacement will be needed every so often. Goodness knows, it is cheap enough!

Re using zip cord and the like: it is my choice on DXpeditions rather than hauling along bulky coax. For recieving purposes it works just fine with suitable baluns / matching transformers. Yes, we can get all academic and purist but it suffices well for my particular purposes.

Cheers, John

9934. Impedance matching

Hello All,

Boy, the more I learn the less I know when it comes to transmitters/antenna tuners/transmission lines/ and antennas.

Here is a link to Cecil's-W5DXP-site, and his explanation of the function of antenna tuner in an antenna system:

http://www.w5dxp.com/OWT1.htm

He is the guy with the switched in lengths of 450 ohm line as matching stubs, using knife switches, BTW. He really seems to know whereof he speaks, being a life-long EE and all, and antennas are his specialty.

I've read through the link above, and Cecil seems to be saying that the antenna and transmission line form a system, and the antenna tuner matches the whole system, transmission line and antenna both.

I think that Andy makes a good point that the closer that your transmission line matches your antenna, the less work the antenna tuner has to do, and perhaps its insertion loss is lower.

The search for the Truly all band antenna goes on!

Cheers,

Brian

Hello Steve,

Thanks for the link! There is lots of good stuff on that site, in addition
to the info on how tuners work.

Cheers,

Brian

Brian,

Some further information on what a tuner does, here:
http://www.karinya.net/g3txq/tuner_match/

73,
Steve G3TXQ

9937. question for MW loop

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-05-19 19:36:57 UTC
From: LIAGKAS ZAXARIAS
Topic: 9937 Message: 9937

Hello
I m thinking into making a MW loop using this box
http://www.ipernity.com/doc/zliangas/15104891
that has dimensions of

30 x 49.5 x 26cm height (5 cm for the handler)

How many turns do you think are necessary to resonate in the MW band?
I Need this information before i buy the necesary wire ...

A friend has made something similar using a box of 35x52 x 26 height using Ethernet cable with wire steps of 1 cm

zach

I believe it depends on the capacitor you have.
How about trying this calculator:
http://www.angelfire.com/mb/amandx/loop.html

Yes i just tested it and was a little garbled with his winding number> althouth as noticed he used 0.5 inch step , the default number shown in the calculator is 0.05
Does it mean that i have to use the 1/10 of the real spacing??

you don't have to stick to that spacing value
you have to play with capacitance and inductance
a big variable capacitor will help

OK thank you for the info

I have many spare capacitors ranging from 150 to 1500 pf!
The design of amandx reminds my big loop on
http://www.ipernity.com/doc/zliangas/13310480/in/album/282394
that is not easily transferable outside the house

Sometimes my local power line noise is about S8 or so on 80 and 160.
I am considering the purchase of one of these magnetic loop antennas for receiving.
Anyone have one of these ? How well does it perform ? One better than the other ?

Hi Bob,

I could compare both antennas side by side, trust me, the better one is the ALA1530.
Here is a link to a review of both of them. Very comprehensive and interesting. I confirm Guy Atkin's conclusions.
http://tinyurl.com/ogo25st
Like most Pixel users in Europe I sold on my RF-Pro-1B after one month use.
Furthermore WELLBROOK's boss Andy IKIN is very customers-friendly and provides help and advices at any time !
Hope it helps

Dominique
Normandy, France

PS: I don't have any connection to WELLBROOK !

I've used a Pixel Tech PRO-1a for several years. It's mounted on a 5 ft mast section attached to my deck, placing the loop's center ~7.5 ft above the ground. I have the loop parallel to the house where it minimizes the powerline noise. That was to be a temporary mounting, but it works so well there, I left it. It is mechanically stout, having weathered a near-miss by the F3-F4 tornado of 1/27/12. My neighbors weren't so lucky. It did clean off the deck, however. I wish it had a 12V input for the power inserter - I could have listened during the power outages. They have one available now. I've had 145ft lw, TTFD, A-D Sloper, etc - the trees supporting the house end of the antennas had to be downed - too much storm damage. The PRO-1a is more quiet than even the TTFD - with similar signal levels from 2-18 MHz - the directional nature of the small loop makes a rotator helpful at MW and below. Great product - modular construction is a plus - as is the fact it was made in the USA. Check eHAM.com reviews for more ratings.

Pixel's power coupler requires more than 12V because the loop amplifier module has an on-board 13.6V regulator. Given the typical voltage regulator overhead, IR loss in inductors in the loop amp and the coupler, plus IR loss in the coax cable, you need about 18V minimum into the coax cable at the DC coupler end.

Feeding the loop amplifier with higher voltage and employing a voltage regulator at the amplifier end is a design decision to provide the same high level of performance over a range of voltage and temperature.

It is possible to feed the DC coupler with battery power, but since the DC coupler has a bridge rectifier and its own voltage regulator, plus IR drop in chokes, you would need a minimum of 24V DC into the coupler. (This is based on a quick mental calculation; I have not measured the required voltage nor added a safety factor for component tolerance.) A pair of 12V gel-cells in series should be OK, but I have not tested that configuration.

In an e-mail from Doug Talley 3/2/12 of Pixel Technologies answering my query re a 12V power inserter, he replied, "We also have a different power inserter that will allow you to use 12V.". Perhaps the 13.6V regulator simply passes the current with little voltage drop across it's series pass regulator and combined IR losses. At any rate, I'll patch up a simple inserter and try it.

9948. The Kaito KA-35 Active Antenna people need to know about.

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-05-24 10:06:51 UTC
From: richnlewis
Topic: 9948 Message: 9948

The Kaito KA-35 Active antenna is good for some DXing. I use a KA-1103 for some SW DXing and to improve local AM station reception occasionally. According to GCC Engineering on medium wave and Long wave the antenna is a untuned Antenna and can be modified to replace the untuned amplifier with a loop for AM and LW This is what I am looking for is to improve LW reception. On Shortwave the KA-35 with the whip is no better than using the whip antenna in my Kaito KA-1103. This has been discussed in a file on the longwaveradiostationlistening forum on Yahoo Groups under files - LW Antenna Projects and Experiments There you will find a file called GCC Engineering-KA-35 Antenna Tips.zip. These will give you some ideas on what you can do for MW and LW. I do have some ideas for what I want to do.

Since I came up with this first and posted it on the long wave group, we need to work on it together. First, for this to work. The KA-35 antenna is a untuned broadband antenna amplifier, you can make alot of these using a J-FET or 2N3904 transistor.

The antenna that uses to tune the antenna is the Radio Shack Amplified Antenna with 2 modifications and that is changing the coils in a unused amplified antenna such as changing the 0.68 uH coils to 2.5 mH for L1 and 470 uH for L2 or 150 uH.

I added a 3 way switch and connected the inductors (2.5 mH - 470 uH - 150 uH) in series with the switching circuit. The KA-35 is a broadband active antenna and you can add in series a MFJ-956 or this experiment. The 20-280 can go as as low as 30 kHz, but the J-FET might need to be changed to expand even lower.

2.5 mH - 130 kHz to 320 kHz
470 uH - 320 kHz to 600 kHz
150 uH - 600 kHz to 1.8 MHz

9950. Looking for BCB Antenna - Ribbon Cable

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-05-25 23:37:35 UTC
From: dziki64
Topic: 9950 Message: 9950

Hello. I'm looking for an article/website that made a broadcast band loop antenna using computer ribbon cable. I believe it used about 10 or 12 rows of the cable.

Any ideas?

Thanks!
Marty

Bruce Carter had a 3 foot box loop that had about 12 "turns" of ribbon cable similar to the carpet loop but of smaller dimension. Can't locate that particular page now.
Earthlink/Mindspring has shutdown Bruce's site due to exceeding his bandwidth cap.

I can't help with advice on the antenna, but I can help with web hosting. I have a web hosting account and if Bruce wants to pay the $10 a year the domain name costs I would be happy to host his site under my account for free. I host a number of sites for friends. If Earthspring doesn't like his bandwidth usage, that won't be a problem with my account. Are we talking more than a TB per month? I was using nearly that much at one point and it wasn't a problem.

Rick

9955. QST on transmission lines

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-05-26 15:47:15 UTC
From: Brian Burns
Topic: 9955 Message: 9955

Hello All,

Since we had a lot of discussion recently on transmission lines, I took special notice of an article in an old back issue of QST. "My Feedline Tunes My Antenna" by Byron Goodman W1DX is in the March 1956 issue. It's an excellent article on the fundamentals by one of the all time best ARRL writers.

You can download it from the ARRL site if you are a member, but if you are not, let me recommend AMForever. Register for free to this excellent forum, and click on Publications. You get access to scanned copies of ALL of the back issues of QST and a number of other ham publications as well. If you are interested in AM and Boatanchors, as I am, there are a bunch of well informed and helpful guys that contribute there.

Cheers,

Brian Burns

9962. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-06-01 20:21:09 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 9962

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1. * Justice AM Loop Antenna (Active)
> - - - discontinued
>

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

9964. LOOP AMPLIFIER

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-06-01 19:04:37 UTC
From: n0sa@att.net
Topic: 9964 Message: 9964

I recently received the AAA-1B loop amplifier from LZ1AQ.
http://www.lz1aq.signacor.com/
I must say that this is a very nice amplifier and so far I am very pleased with my purchase. Total price with shipping to the US was about $120 and I think it was a real bargain. It has multiple options for hooking up different loops and dipole elements. It is shipped with the amplifier in a nice waterproof case and the matching/power inserter unit. He uses shielded cat5 wire to carry the RF, control signals and supply voltage to the amp. This is a unique way to do it and I like it a lot. Cat5 shielded is pretty inexpensive and the connectors are reasonably price too. Being an Electrician I am familiar with these terminations and have installed hundreds of them.
The documentation on the webpage is top notch and gives a few examples of possible antenna configurations and the pros and cons of each. I tried the double vertical loop setup with two 5/8" copper tubing loops about 28" in diameter. Just playing with it in the backyard I was able to see how good it really works. Reception was good and the nulls on local BC stations was very sharp and deep.
I was so impressed with the quality and the possibilities that I ordered a second amp so I can do A-B testing with different configurations.
If you like loops and like to play with them then this is a great platform to experiment with and come up with a nice antenna for your location.
I have no connection with Chavdar (LZ1AQ) other than some nice e-mails and a great product. Just wanted to get the word out about what is in my opnion a very nice product.
Check out his website for all the information.

<<SNIP>>

I've seen the schematic for this in the one article linked on that web page. Nice, simple design that shows that he understands the need for a very low input impedance amplifier for wideband active loop antenna operation. Much less costly than the one I designed, though mine undoubtedlt has better IMD and NF performance.

From: john
Topic: 9964 Message: 9968

Hi Larry,

I have mine set up as a simple loop and have not played with some of the other options. My loop is a piece of flat aluminium strip placed inside a 3 metre lenght of 25 mm plastic piping, bent into a circle and held together with a T piece. Leads were attached to each end before bending to be brought out and attached to the electronics. when bent. Can send a pic if the description is a bit obscure

. My Dx friend across town used the same technique which is simple, robust and cheap.Very sharp nulls and works well with the loop amp.

Cheers, John

John
Thank you for the information.
I have mine set up in the dual vertical loop configuration.
I used two 5/8" copper tubes about 28" in diameter and get very deep nulls on local NDBs and local BC stations.
I also want to try out the dipole options.
I may even try some bigger loops made with dual copper wires.
Chavdar gives some good suggestions and information on the pros and cons of each style on his website.

9971. Palstar LA-30 Rotating Loopstick Lowband RX Antenna for sale

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-06-05 02:05:12 UTC
From: William Hein
Topic: 9971 Message: 9971

I purchased this high performance, ruggedly built loopstick antenna in 2010 and never got around to using it. I now live in a house that is partially underground (not good for indoor antennas) and have room for Beverage antennas so this - new condition, only used to test performance - unit is for sale along with the the accessory plug-ins loopsticks for long wave (110 kHz to 550 kHz and tropical band (1480 kHz to 7.5 MHz). Note the base unit covers MW 410 kHz to 2.05 MHz.

From the Palstar Website:

http://www.palstar.com/en/la30/

"The new Palstar LA30 Ferrite Loopstick Antenna is designed for the avid LF, MW, and Tropical Band SW listener. The LA30 is a rotating loopstick antenna using active electronics to give high selectivity & gain. The tunable pre-selector ensures best possible weak signal reception and interference rejection.

"A hi-Q pre-selector eliminates interference from powerful nearby stations. A +15 dB pre-amplifier pulls in weak stations, while a 15 dB attenuator prevents overload when listening to strong stations. Rear switch can select either wall transformer input or a 9V internal AA battery pack.

"Add 11 Ga. (.090" thick) iridite-treated aluminum metalwork and durable powder coated finish on the front panel and top cover, and you have the LA30."

Would cost you over $510 today, will sell for $399 plus shipping and insurance (or you pick up near Grand Junction CO). Non-smoking shack. Serial number 14929. PayPal preferred or will take check or Wal-Mart money order.

From: john
Topic: 9964 Message: 9972

Hi Brian, the aluminium is simply a standard size strip of about 25mm x 3mm x 3m long. Will post a photo in the next few days. Imagine a piece of plastic pipe bent in a circle with each end secured in a 'T piece'. the aluminium strip is placed in the pipe before bending it around ie it is inside the pipe and bends along with it. Make sure connection wires come out through small holes drilled in the joiner. Connect one to each end of the strip, drill a small hole in each end of the arms of the T. Feed one wire from the inside to the outside, secure that end of the pipe in the T piece, bend the other end around into a circle, feed the other wire connection out through the hole on the other side then secure the pipe into the fitting.

At this point you should have a length of plastic pipe bent into a circle with both ends secured by the T. Inside is a flat aluminium strip with a wire connected to each end coming out through small holes drilled into each arm of the T. That is your loop ready to connect to an enclosure with the electronics inside. It should be easy to use standard fittings to mount it on a support.

All the pieces were just standard fittings from the hardware store's plumbing section. Total cost was maybe $25 and the whole thing is light and robust. Add LZ1AQ's loop amp and some CAT5 cable and I have a wellbrooke equivalent for maybe a third the cost of importing one. This is a great recieve antenna and has the advantage that I can knock down the local pest with a sharp null.

Cheers, John

John,
Thank you for the response to my query, most kind.
Your 25mm x 3mm flat strip I make equivalent to the surface area of
an 18mm dia tube in RF skin terms which is about the same diameter
as Welbrook use for the ALA-1530 !!!!
Certainly our local DIY warehouse sells strip in 3m long lengths so
will check out the cross sections available.
From your clear description assembly sounds straightforward,
the secret being not to lose the wire tail hi!
As a matter of interest I had similar thoughts on using a 3ft dia plastic
' Hula Hoop ' with rolled up turkey strength cooking foil as the core
these are just the correct dia to fit into PVC 18mm electrical conduit
fittings like ' T's, junction boxes, elbows etc ' which has the advantage
of being much stronger than PVC water pipe.
To date I have never heard of anyone who has taken a Wellbrook ALA-1530
apart !!!!!
I will let you know how I fare with my version of the loop.
My particular interest is NDB and 28 mhz beacon monitoring.
Your comments on nulling the local ' pest ' out is of much interest
as I have 349.5 khz - Liverpool just 8 miles away, a real pain !!!!!
Regards,
72, Brian, GØNSL.

Brian,

The loop amplifier in question has a very low input impedance, hence there will be a miss-match at MF and HF when using a loop with the above dimensions. Whilst this may not be an issue for just nullinng out a pest. There will be noticeable loss in s/n compared to Pixel and Wellbrook loops that use higher input impedance amplifiers.

A very low input z amp. requires a much lower reactance loop. This is not easy to achieve whilst maintaining a reasonable capture area.

Earlier this year I received updated Calibration data for the LFL1010 (same amp as the 1530, but a much lower input z) and compared it to the ALA1530. The net result was an approx. 10dB improvement is sensitivity at MF and HF with the higher input z ALA1530.

Kind regards

Andrew

Hello Everett

Thanks for the tip about your PDF on this subject, which is really, interesting. Regarding the use of two coils with a working loop, from my personal experience, they do work very well. Intact, I had a small wire loop receiving signals with two large wire coils distal to the end feeds. The loop was just 14meters in diameter and the child fed into an unun. This antenna was really good too, many shortwave listeners were contacting me to advise that they were witness to my DX.

As for all electrically short antennas, they do work very well, especially for users who are limited by space!

Please can anyone advise on where around 20 meters of PEX tube, 32mm diameter, can be purchased in the UK?

Regards

Stacy

From: Editor
Topic: 9979 Message: 9979

Question:

Where is the best place to mount a magnet loop antenna (it is two Hermes 1.2 Meter loops phased together - 4 meters separation - fairly directional)?

I am thinking to mount the system on our office complex roof which is a fairly large flat surface with a few HVAC units on it. Mounting up on the roof provides a bit of safety from all the copper thieves who are going through office parks these days and stealing whatever in not screwed down.

The antenna would be about 20 feet above the parking lot and we are located right next to the San Francisco Bay with nothing to the west of our complex except water. All the roofs in the area are about the same height as ours. I can send photos if needed.

Ideas and comments always welcome.

Thanks.

Kevin

Kevin...My only advice would be to mount the antenna as close to the center of the building as possible in order to avoid detection from the copper thieves you have mentioned.I have read that at 20' and above ground level,it should be mounted in a horizontal configuration.It sounds like it will work well from that geographical location.Dennis W7KB

Hi Everett,
txs for uploading your pdf file on the dual coil loop.
Could you please specify more how you attach the 2 coils together with "hollow nylon spacers"..? Perhaps a picture could explain everything...?
Txs for your time answering my question.

Kind regards

Tony

9982. Half Loop Mag Mobile Antenna

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-06-16 20:07:29 UTC
From: Gian
Topic: 9982 Message: 9982

Hi all,

I have just joined the group.

I am looking for a project/guidelines to homebrew a mobile half a loop HF antenna for emergency communications, to be mounted over a car roof. The antenna should cover al least 40 and 80m, with potential use on 160m. We expect to use at least 50W RF or maybe 100Wrf.

Any experience with such a kind of antennas?

A search on internet gives only a couple of commercial antennas.

Thanks and best 73

Gian

There are some antennas like that mentioned occasionally on the [NVIS] Yahoo!group.

Because they are electrically small on the lower HF bands, and close to the ground, they tend to be rather inefficient. But if you need to operate mobile on those bands, it is an option to consider.

The commercial versions tend to be very expensive. Perhaps more than a top-of-the-line radio would cost.

There are occasional links to pictures of homemade versions, usually without much detail. Radiation resistance tends to be low, so good bonding to the roof/vehicle is crucial. Don't think of it as mounting an antenna on your car; think of it as modifying your car to accommodate the new addition.

A loong time ago, QST had an article titled "The Connecticut Long Horn Antenna". Maybe that is what you a looking for.

Whatever loop you build, you need to decide whether you want horizontal or vertical polarization, which is determined by where you feed it.

Hi All,

thanks for your replies.

I am looking for a half mag loop to be installed over a car roofrack. Yes, I understand the car will become modified.

Certainly these kind of antennas have not the best performance but maybe not wortse than a very short mobile antenna positioned at 45° over the car roof or like the one in the QST article.

My basic questions are:

1) How is the capacitor value calculated and the minimum required voltage

2) what should be the minimum width of the half mirror side

3) what it will happen to the rf current over the car roof?

I have found several NVIS groups in yahoo. I enrolled in one nott too large, but the majorities have a very few members.

The main NVIS group is simply "NVIS". It has well over 1000 members. It is not listed in the Yahoogroups directory (a signup group is listed instead, making it a 2-step process), but you can go directly to the group. Just substitute the word "NVIS" in the URL for any other Yahoogroup's name.

just use yahoo’s own search engine. go to your groups page where all your yahoo groups are listed and above them you’ll find a search box. pick a group that has lots of folks and they are active ,unless all you want is to look into there files n links.

That is the "sign-up" group, not the real one. It will get you there
... eventually ... if you follow all the steps.

You can bypass that step by going directly to the NVIS group itself,
which is named simply "NVIS" instead of
"NVIS-NearVerticalIncidentSkywave".

(The reason for the multi-step process is to try to keep spam-bots
from joining the "real" group.)

Here are a few other (smaller, less active) NVIS-specific groups I know about:

NWNVIS
HFNVIS
NVIS-Antennas
International_NVIS_Association

These are all Yahoo!groups.

A number of years ago, somewhere on the "NVIS" yahoogroup ... either on the group's site itself or in links to other sites ... there were pictures of a couple of vehicles with half-loop antennas welded on. Patricia Gibbons, one of the group's founders, who passed away a few years ago, had pictures of hers. IIRC she used an SGC antenna tuner at the feedpoint.

I don't recall seeing much in the way of theory or math.

Hi All,

thanks for your feedbacks. THe NVIS request via mail, as suggested on the group did not work out, I got delivery error.

Yes, I have seen groups witha few peopleand not active. There is one group with over 10000 members ...too many but I will try there.

What I may try is to build an antenna with mechanical measures that will not be critiocal for cars roof and fiddle around it with a normal capacitor and use an antenna analyser, than, if the results are similar to a standard magloop I can go ahead. We can try with a qrp rtx if it work on tx too.

Try again! If you got a delivery error, it probably means it was sent to
the wrong address. The address for subscribing to the NVIS group should be:

NVIS-subscribe (at) yahoogroups.com

substituting the '@' symbol for the "(at)". (I wrote it that way because
Yahoo sometimes obscures email addresses within group messages.)

If you prefer to subscribe via the web, go to
http://groups.yahoo.com/group/NVIS/join but you will need a Yahoo account
to do that.

Regards,
Andy

From: Everett
Topic: 9999 Message: 9999

Hey Guys,

If anyone is interested I have 3 Broadband Active Loop Antenna boards that I made up while experimenting with board layout and evaluating performance. They all work very well using a 9 Volt battery and various wire loops from 1 to 2 meters in diameter. Two of them are using BC547 and one has 2N2222A transistors. They were all built Rat Shack perfboard

I would like to sell all 3 them to help cover the cost of parts and my time building them. I am asking $35 each plus postage. I would never build them and sell them at that price.

So if anyone is interested please contact me off list, erverettsharp@... and I will send you a wiring diagram and pictures of the Broadband Active Loop Antenna boards.

Thanks for your rely.

Yes, I did visit that site. The only problem is to understand how the half a loop works, i.e. what happen to RF currents un the mirror part of the loop and on the car real roof.

I will try to figure out the capacitor formula from the 14-30MHz example.

Thanks and best 73

For a half loop that connects to the roof on both ends, at the very least you have the loop current itself which completes its circuit via the roof. There would be some spreading out of the current in the roof, depending on frequency, I suppose.

Many mobile loops are complete loops that happen to rest slightly above the roof. That's a good question what happens in the roof in that case. I bet it depends a lot on loop orientation. Most of these small mobile loops are vertically oriented, but I have seen horizontal loops above the roof too. It would seem like the roof causes a "shorted turn" that is close coupled to the loop, which is probably not good.

Andy

I have a two bars roof rack across it (add-on). Would it be necessary to connect the loop mirror side to it or isolate it as strong current may spread ???

10003. Questions for the loop experts for MW Dxing

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-06-30 00:46:05 UTC
From: neilbell99
Topic: 10003 Message: 10003

1. What is the main factor in determining loop nulling ability? Size of the loop, sharpness of tuning (Q), spacing of the wires, shape (Round or square), number of turns, etc.

2. Is there a significant difference in nulling effectiveness between an air-core loop and a ferrite bar antenna (like the twin-coil sold by Crane)

I want to buy (or make) a loop with excellent directivity, maximum size about 16 inches. Tuning capacitor of pretty good quality.

My receiver is fairly selective but some amplification would help a lot for the distant low power Graveyard stations.

Obviously something like the famous KIWA loop would be nice, but they are very hard to find and quite expensive.

Advice, comments or suggestions greatly appreciated. Currently I use a cheap Kaito an-100 loop directly connected to my Yaesu receiver.

Neil BEll, KJ6FBA

10004. Spectracom 8206 Loop Antenna

Yahoo group: loopantennas (2013 — 2017)

From: Dennis Tillman
Topic: 10004 Message: 10004

Hi Everybody,

This is my first post to this forum although I'm a 10+ year member of the TekScopes Forum so I know how this works.

I have a Spectracom 8206 Antenna (Spectracom calls it a loop antenna, but I would call it a ferrite rod antenna) which worked fine until a few years ago. I took the antenna apart to troubleshoot it and at that point I discovered it was modified by the previous owner. I have not been able to figure out what the modifications were for and I have not found the problem that caused it to stop working. While troubleshooting it I inadvertently lost one of the transistors while I took it out of the faraday shield to test on a curve tracer.

Does anyone out there have a schematic for the preamp on the faraday shield inside the antenna? I have the manuals for the Receiver, the Phase Comparator, and the Chart Recorder but I have never found the schematics for the antenna itself. Spectracom was no help. They long ago stopped supporting it and insist that all documentation has been tossed.

John Ackermann (one of the expert TimeNuts) did a test of this antenna which indicates its combined Q is on the order of 1000! So it is not something that I would want to try and repair without having a schematic handy to see what the designers were thinking. See this for details of John's test:

http://www.febo.com/time-freq/wwvb/sig-strength/spectracom-antenna.html

Thanks, Dennis

The National Radio Club has some good handbooks on building a
good receiving loop for MW DXing.

My experience has been for best nulls you want a BALANCED loop.
That means one side of the loop is not grounded. Both ends of the loop
are above ground with a center-tap, usually used with a balanced preamp.

Tuning capacitor should be mostly symmetrical, not one side connected
to a big metal frame.

Using one of the newer one-turn broadband active loops solves many
problems. No tuning capacitor is used so the loop is well balanced
electrically.
Single-turn broadband loops have excellent nulls. No cumbersome remote
tuning capacitor needed if mounted outdoors.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1. * Justice AM Loop Antenna (Active)

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

10007. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-07-01 14:55:58 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 10007

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Steve Greenfield

10008. c-crane dual coil antenna?

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-07-02 07:39:59 UTC
From: Vojtech
Topic: 10008 Message: 10008

Hello.

I stumbled over a patent US 6,529,169 B2 from C-Crane.
http://www.google.de/patents/US6529169

The patent claims, that:
"However, when a signal enters a ferrite rod antenna that is tuned to resonance with a coil and capacitor, the magnetic lines of flux begin to saturate. This is due to sympathetic resonance. ..... When this saturation occurs in a ferrite core antenna, the ferrite rod antenna takes on polarity, much like a standard magnet. Ferrite antennas of the prior art have only one pick-up coil, and this coil receives the sympathetic resonance from only one-half of the ferrite rod. This results in loss of efficiency and limits the signal-to-noise ratio available to the receiver electronics."

The patent sais, the two coils are wound in the same direction and connected in series. It looks to me like an analog to a single turn loop antenna with a capacitor at one side and a current transformer at the other side. I suppose the setup improves symmetry, but it eludes me how it lowers saturation at resonance, and the patent claims that the improvement is more pronounced at higher frequencies.

I wonder how the setup compares to the PalStar LA30
http://www.palstar.com/en/la30/
see te schematic here:
http://www.palstar.com/manual_la30.pdf

The PalStar LA30 works very similar in my opinion, the main difference being the coupling of the amplifier to the loop resonant circuit, where the C-Crane design is coupled with a transformer between the cols, while LA30 is coupled symmetrically at the ends. The C-Crane coupling may be more symmetric, but the way it is tuned with a single varactor at one end of the ferrite rod, the other end of the other coil grounded, it does not.

The patent also claims:
"Ferrite antennas of the prior art have only one pick-up coil, and this coil receives the sympathetic resonance from only one-half of the ferrite rod. This results in loss of efficiency and limits the signal-to-noise ratio available to the receiver electronics."

This souns like a wishful thinking.

Any opinion?

Thanks and 73, Vojtech OK1IAK

10009. Re: c-crane dual coil antenna?

From: Bruce Carter
Topic: 10008 Message: 10009

The CCrane EP radio has built in twin coil ferrite bar. It is not as sensitive as a GE SR-3 which has a single coil ferrite bar antenna the same size. I can only assume that it is the ferrite that is doing the work of concentrating flux in the coil, not the coil set.

IMHO, this is total nonsense. There is no way a ferrite rod,
with its huge air gap, is ever going to saturate on receive
signals. In fact, you couldn't make it saturate if you tried
to by putting DC through it.

The crane antenna have a twin coil, is like a single coil with a middle derivation

as the preamplifier is balanced the middle point of the coil is for work as a balanced coil to attach balanced preamp.

I will build a clone of the preamplifier for test it with my air-loop

The LA-30 looks very similar to circuitry used as far back as the 1970's, either home built, or sold commercially as the Radio West Ferrite Loop antenna, which used different coils to cover LF, MF and HF.

http://www.jlkolb.cts.com/site/dif_fet.pdf

The original circuit was probably done by Gorden West of National Radio Club.

I would think the two coils, to resonate with the same capacitor, would have the same combined inductance, and thusthe same number of turns as a single enter tapped coil, so the same voltage induced by the RF.

This same topic came up several years ago. At that time I bought the Twin Coil antenna and tore it apart and tested it extensively on the bench. I used both the original twin coil then replaced it with a single coil. In all tests, there was no significant difference, if any differences at all, between the two configurations. And reading the patent, there are glaring errors seemingly purposely inserted to try to fool the unwary. It's a good antenna for its 7.5" ferrite rod size and works well and I recommend it if one needs a 7.5" ferrite rod remotely tunable antenna. But if you homebrew your own using a similar 7.5" rod from Amidon, and the standard single coil, you'll get the same performance. There is no magic at all in the use of "twin coils". If anything, it appeared the technician on the factory production line could more easily and quickly adjust the antenna for the proper tuning range, compared to a single coil--perhaps that's the main reason why the "twin coil" continues to be made.

It's similar to what xtal radio developers have been using - multiple air-wound coils in the same plane to help increase sensitivity to their crystal sets. The use of the ferrite bar allows a reduction in the coil size. Difference is that the crystal sets do not fix the position of the coils to allow for fine tuning of signals. I do similar using a Terk Advantage coil with my portable radios. It works but it is not a miracle worker.

Kevin,

I would much appreciate it if you would supply links to a site or two where one can learn more about Xtal set builders use of multiple air-wound coils in the same plane.

Thanks,

Tom

Hi Kevin,

If you will look in the files section I have several articles that I have posted that will give you a lot of information on multi-coil loop antennas, where I have made various configurations with 2 and 3 coils in parallel as well as a Pollydoroff configuration. All of the various configurations, using more that one coil have made an improvement in performance over that of a single coil. Most of the experiments were done on either a Ferrite Sleeve Loop (FSL), or on Sstacked Toroid Loop Sticks (STLS). You will find them listed under my everettsharp74 email address. However, I do not use that address as my primary address, it is everettsharp (at) aol.

10018. Wiring diagrams/schematics for a Broadband Active Loop Antenna

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-07-05 15:46:58 UTC
From: Everett
Topic: 10018 Message: 10018

Hey Guys,

Does anyone have any wiring diagrams/schematics for a Broadband Active Loop Antenna, other than the two that are currently on the web, the M0AYF and LZ1AQ, both of which I have built and am wanting to try some other designs that might be better. So far it looks like the LZ1AQ has a lower noise floor than the M0AYF design. However, both designs work well. Would be nice if someone had a schematics for Wellbrook or Pixel, or something else along those lines.

Please send me anything of interest to my direct email address, everettsharp (at) aol.

This loop antenna amplifier of mine will outperform the Pixel and Wellbrook products:

Chris,

Why is this better than the Wellbrook solution? I would be very interested to learn more. I think their designs have an impedance tracking circuit that matches the loop to the amp.

Mine has better IMD performance, the result of adding augmentation to the common-base amplifier stages. The design sees the loop as a current source, so the amplifier only needs to have a very low input impedance, much the same as the design by LZ1AQ approaches the matching problem. You really don't want to try see the loop as a voltage source and try wideband matching it to a fixed load:

http://www.home.earthlink.net/~christrask/Wideband%20Loop%20Antenna%20Matching.pdf

Been there. Done that.

Thanks Chris,

Now I have a few questions: For Q1 through Q5 could I use 2N2222A, or BC 547, rather than the MPS6521 and could I use something like a MPF102, or J310 in place of the PN4416 in Q6?

Also could I use BN 73-202 for T1, 2, 4 & 5 and could it also be used for T3 and 6?

It does no have to be perfect, I just want to try it using some of the crap that I have in-house, without having to look all over the place for parts. It always cost more for shipping than most of the parts. You never can find all of the parts in one place.

One last question can I eliminate everything left of C2 & C3 and all of the L's use ferrite beads, I think that I have some 102 on hand.

Hello Everett,
Here I have two designs - in fact two versions of the same concept - of active broadband loops.
The first article is in Dutch, but you will understand the schematics, the second site is in English, but you have to register. Nothing awkward will happen if you do.

As requested. Not trying to be a smart-A but these are two that popped up readily.

http://antiquewireless.org/otb/dxxtal.htm
http://members.shaw.ca/ve7sl/crystal.html

If you notice the coil construction, there are a couple of techniques being used. One is a basketweave type construction and the other is the normal spiral wrap on a coil form. By not having the coils fixed in place as in the Twin Coil design, you can adjust the coupling between the coils to peak what you are trying to listen to. I suppose you could manage to alter the distance between coils on the Twin Coil design but then you would not be able to use the weather proof case for remote mounting! I suppose you can probably come up with similar results using separate loopstick antenna coils.

Makearadio.com has instructions on winding basketweave antenna coils, larger frame type coils, and spider coils.

Kevin,

Many thanks. From your earlier message I assumed that you had more information about the Xtal set builders at hand than you did, and didn't realize that you would need to do a search to answer my request. This dumb-A could have done that. I appreciate your effort,and sorry for the trouble. The links are a great starting point.

No Problem!
With work being so busy, things have been falling out of the bit bucket so I have had tendency lately to just refer to things off the web (with a reasonable sanity check). Saves on "now what file did I put that under ??" ! Those are a couple of sites, with included links that I refer to when trying to look up crystal sets and I don't mind sharing. I am going through those again as I am researching antenna coils to use for building a Tuned Radio Frequency (TRF) radio. I found a ZN414 TRF IC and trying to figure how I want to build the "front end" without buying a ferrite loopstick antenna. There are inherent weaknesses in the radio and chipset design and i also have to worry about a 50KW flamethrower 3 air miles away from me. The links also show how to build bandstop filters which will help attenuate, but not eliminate, the strong AM station (KNX-1070KHz).

From: leblanccamloop
Topic: 10032 Message: 10032

Hi gang,

I just had a crazy idea and was wondering if anyone could comment on it. I have been looking into building a 60 foot by 22 foot delta loop for primarily LW/MW and from what I've been reading they tend to be good low noise antennas. However I don't need it to be directional and would prefer it to be more non directional. Here comes the crazy idea: Would it be possible to run half the loop in one direction and the other half about 90 degrees from that direction using the apex support point as the pivot point? What effect would this have on the antenna sensitivity, pattern and feed point impedance? The terminating resistor would therefore not be selected to give any deep nulls as this is what I don't want. Would the standard 1.2K ohms be a good starting pojnt or perhaps a bit lower in value? Any advise would be appreciated.

Thanks
Cam

Cam, you will probably end-up with a pattern that where the null is slewed at 45 degrees. An omni-directional pattern is only possible with two orthogonal loops that are combined at 90 degrees. I would recommend that you stick to the normal Delta.

As a guess your loop will have an inductance of 70uH (1.7uH/m), thus the impedance will be approx. 70 Pi Ohms at 500kHz or 220 Ohms. So a simple 4:1 z Balun will do for the 50 Ohm Rx. Make the balun input centre tapped and connected to the feeder to maintain the loop is balanced to reduce the E Field response.

Another point try the keep the loop circumfrence no larger that 0.2 Lambda at the highest frequency.

Kind regards

Andrew Ikin

Hi Cam.

I am a LW NDB Dxer. You will want directionality but it will somewhat broad in my experience anyway except for a few degrees around 90? to the plane of the antenna. I assume your length is 60ft on the ground. Why not make two 30 x 22ft 90? apart? If you are going to DX MW stations I would think you would want some directionality.

My ALA100L's are 30Lx12H (ft), 4ft off the ground rectangles 90? apart. I have 4 support masts but you could get by with 3. Use large diameter stranded wire like 14 or 12ga (US) or even large gauge twinlead or windowlead to increase the surface area of the wire (ends connected together). They could be lower but I have mine at 4ft to make it easier to cut the grass and what not.

I'd like to use 1/2in or 3/4in copper or aluminum tubing but it would probably get stolen and possibly become an eyesore to some neighbors. I painted the masts to match the house color and used black wire. Practically invisible from a distance.

From: Camille LeBlanc
Topic: 10032 Message: 10036

Thanks Don and Andrew for your replies. You have both given me food for thought. I have recalculated my planning and I now think I will build a regular form delta 41 feet long by 18 feet high. This should reduce my old circumference from 134 feet (41m) to around 95.5 feet (29.1m). It would be built along the back fence and be feed from the ENE end therefore nulling the backside New England states. (I'm in SE New Brunswick, Canada) This should give me a better shot at TAs.

Andrew, I was intregued by the way you calculated the impedance. What formula did you use. I would like to recalculate my new design at various frequencies. I was also planning on rolling my own impedance transformer on a 100mm ferrite rod but from what I've read it is recommended to isolate both windings and not tap a single winding. (perhaps I misunderstood what you were telling me). I presume the smaller circumference would raise the feedpoint impedance from the 220 ohms you quoted me.

Thanks again gentlemen
Cam

(perhaps I misunderstood what you were telling me). I presume the smaller circumference would raise the feedpoint impedance from the 220 ohms you quoted me."

Carmile, generally speaking, 1m of thin wire has a measured inductance of 1.7uH. The Impedance is 2Pi F x L where 2Pi is 6.28, F MHz and L uH. Hence at 1MHz a 1uH inductor has a reactance of 6.28 Ohms. I would recommend that the transformer should be constructed using 10 turns turns trifilar 36 SWG (0.2mm) enamelled copper wound an a Fair-Rite twin hole core 2873000302. The antenna side is 2 x 10 turns in series, so you will have a centre tap. The receiver side is the other winding. Note; type 73 ferrite is conductive so you will need use 3mm nylon insulation sleeving in the core. Alternatively you could use Fair-Rite 28430000302 core, this has a much lower AL value (2uH per turn based on 10 turns) but it is non conductive. If you do end up using a Ferrite rod, then use isolated windings close to each other. Also the ferrite rod needs to housed in screened enclosure. It must be large enough so that the rod is several diameters from the metal work.

A smaller loop circumfrence will reduce the impedance.

Don mentioned the Wellbrook ALA100, this has been replaced by the ALA100LN. It has 8 Fets configured using Gate Source feedback, thus dynamically reducing the Fet Channel resistance and noise figure to a fraction of a dB with low IMD and high gain.

Kind regards

Andrew

Hello again,

Well Andrew and Don, I just finished building my broadband terminated delta loop this afternoon and all I can say is WOW!!!! This is one quiet antenna. I did a quick daytime frequency sweep with my R75 and I heard beacons and MW stations that I don't normally hear on my noisy
random wire antennas. I modelled it after an article written by Bruce Conti in the March 2013 edition of Popular Communications magazine. Matching transformer has 24 turn primary and 6.5 turn secondary on a ferrite rod. Feedline is RG6. Signal levels tend to be a bit lower than what I was expecting, necessitating the use of preamp 2 most of the time but the sheer quietness of this antenna more than makes up for the slightly lower levels. Eventually I will be phasing the loop against a contra-wound helical vertical inspired by Graham Maynard. But for now I will just enjoy it the way it is. I want to thank you both for your replies, insight and help on this matter and thanks also to Bruce for the excellent article.

Kindest regard
Cam

Hello Mike and Group

I am a member of Royal Signals Amateur Radio Club and have been reading the article in this July 2013 journal regarding G4HOL horizontal loop.
My query is the connection of 300 ohm slotted ribbon to an ATU. It states that one leg should go to the Antenna post and the other leg to the earth tag.

Does this mean using wire (A) from one end of the cable loop and wire (B) from the other end of the cable? Alternatively should the one end of the cable be short circuited across the two legs and the other end of the cable be used to connect to the ATU?

My other question (being new to loop antennas) is that a group exists dealing with Magnetic Loops. Are these loops completely different to your loops or would it be better to have just one group to include all types of loop antennas?

I must apologise for questions of this nature but my tendency is to know precisely how things are done.

Regards John 2E0KUF

Loop antennas are magnetic loops, and magnetic loops are loop antennas. "Magnetic loop" just references the fact that a loop antenna is mainly sensitive to just the magnetic field and not the electric field of an incoming radio signal.

Sometimes people want a group revolving around a specific type of loop antenna, sometimes they don't understand that a "magnetic" loop is just a loop antenna, sometimes they don't like the moderator, sometimes they just don't search for a group before starting one, sometimes their group starts as a local club's group and expands. Sometimes a person wants to market their own loops or parts, and so starts up a group of their own. Sometimes a person is a little nutty and starts multiple groups, each covering slightly different antennas, just to be in charge of a lot of groups.

Hello Steve

Thanks for the reply. It was only due to reading the Royal Signals article on horizontal loop antennas that led me to your Yahoo group. Up to then I didn't know it existed. I am a member of various groups relating to Ham radio and find them very useful. What I like about the groups is that every question that I have asked is answered in various ways and this has helped to grasp the technical jargon more easily.

Your answer to my question was both enlightening and amusing. I will endeavour to read the emails since joining your group

In my opinion, a "Magnetic Loop" antenna is a distinct species and they are better left alone as a separate group. Contrary to the name, and contrary to intuition, a Magnetic Loop antenna is not one that generates only a magnetic field, or that is sensitive only to a magnetic field. It has even been shown that many Mag Loop antennas are actually the opposite, responding somewhat more greatly to the electric field than the magnetic field.

I believe the distinguishing feature of a Magnetic loop is one whose total circumference is much smaller than one wavelength ... perhaps no more than a tenth of a wavelength ... such that the current magnitude and phase around the loop is everywhere nearly the same. This is in contrast to "full size" loops, quad loops, delta loops, horizontal skyloops, and such, where the circumference is usually comparable to a wavelength, or longer. A consequence of this difference, is that a Mag Loop antenna has totally different radiation characteristics to a non-Mag Loop antenna. The directions of maximum radiation, and of the nulls, are reversed!

So even though a Magnetic Loop might be considered "just" a loop, I put to you that it isn't, and that it is best treated separately.

About your question about the connections, it's a little hard to tell what you mean, and I don't have access to the article. It doesn't make sense to connect wires from opposite ends of the feedline to the ATU and earth. Same end only.

Articles about the Skywire horizontal loop describe using it two ways:

On higher frequencies (most bands), keep the two ends of the loop separate.

On lower frequencies (usually meaning 160 meters), where the loop is too short to be an effective loop antenna, short the ends of the loop together, or the two wires of the feedline together, and drive it against earth. What you really have in this case is not a loop antenna anymore, but a vertical antenna (the feedline), with what was your "loop" acting as a capacity hat. It's a way of "cheating" ... getting an extra band out of that copper where it doesn't make a good loop antenna anymore.

Andy

10046. Loop Circumference

Yahoo group: loopantennas (2013 — 2017)

From: Hilt
Topic: 10046 Message: 10046

The recommended circumference for a loop is 1 wavelength at the lowest frequency of use.
For a 40m (7.1Mhz) loop this equates to 30000000 / 7100000 (velocity of light in free space divided by frequency) which works out at 42.254m (138.63 ft)
The standard formula is 1005 / 7.1 = 141.55ft. This is around 3ft too long assuming a velocity factor of 1 in both cases.
I would appreciate any comments on the significant difference.

> I would appreciate any comments on the significant difference.
>

It just happens that a loop needs to be a few percent longer than 1.000 wavelength, to be resonant.

It's like a straight half-wavelength long resonant dipole. In theory, the length in feet ought to be 492/MHz. But the usual formula is 468/MHz. Why? Because of "end effect", because the wire isn't infinitesimally thin, because of wire insulation, because of ground proximity, and proximity to other objects nearby. Someone (an engineer at WBZ about 80 years ago) did experiments and found that an average of 5% short is about right ... and so we have 468/MHz. YMMV ... yours may need to be less or more than 468/MHz.

Likewise, the loop needs to be slightly longer than theory says.

Maybe it's because the E-M field takes shortcuts, going around the loop's circumference. Who knows? The point is, people who build loops find that they need to be cut slightly long, if you want them to be resonant.

The difference won't affect how it performs as an antenna. It is strictly a resonant frequency thing (i.e., SWR).

Regards,
Andy

Thank you Andy .... I greatly appreciate your considered response. What you say certainly makes sense to my ageing brain.

Another query that I would like to raise in here is the effect of balanced feeder on a loop's resonant frequency.

If 20 metres of of well-balanced window line is used as the feeder, 40 metres of conductor has effectively been added into the loop.

To my present understanding, the standing wave pattern around the loop must continue down each leg of the feeder which is therefore an integral part of the loop (but with radiation cancelled out).

If the loop and feeder each contain 40 metres of wire, is the combined resonant frequency based upon 80 metres of wire, even though 50% of it is non-radiating?

Taking this further, how reasonable is it to drop a few metres of window line, with its ends shorted, from some point in the loop and expect the loop to perform as if its length had been increased by double the length of the drop?

The reason I ask these questions is that I am in the process of putting up a small horizontal loop where the maximum circumference is restricted to about 32 metres and I want to achieve resonance at the bottom of the 40m band. Experiments show that my Palstar AT2K + 4:1 external balun can tune 6m thru 80m with a 32m loop so I don't know whether there will be a great advantage in trying to achieve 40m resonance by adding a non-radiating length to the loop.

Again, I will really appreciate any comments / advice.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

10053. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-08-01 12:07:34 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 10053

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.

10054. Using loops in combinations.

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-08-01 10:16:01 UTC
From: Maxwell
Topic: 10054 Message: 10054

Most of us have tried loops singular. Has anyone tried loops in combination?
Have used a short length of plastic electric conduit with a ferrite rod held, coaxialy, in each end.
Wound a short coil on the outside of the conduit over each ferrite rod.
Connected the inner end of one coil to the outer end of the other coil, bought the left over ends together at a tuning capacitor.
Tunes ok, however the expected null occurs over only a few degrees of rotation and is very deep.
Conversely, the "acceptance angle" (whatever the opposite of null is) broadens.
Any comments, experience or help appreciated.

Thank you Lionello for your comment. Loops can be used to block the reception of an unwanted station.If a radio/loop combination receives an unwanted station and a physicaly larger loop is interposed between the receiver/loop combination such that the unwanted signal is in the null of the "blocking loop" then when the "blocking loop" is tuned to the station it attenuates the offending signal.I believe that the "blocking loop" absorbs the signal and reradiates it in the plane of the "blocking loop" preventing the unwanted signal reaching the receiver/loop combination. Regards to all, Maxwell.

Hey Guys,

Does anyone have any of the later articles that Brian Greer "Greertech" had on his web site before he took it down. I am looking for anything after "Coax Loop Antennas Operational Notes".

If anyone has this info please email it to me at everettsharp (at) Aol com

Thanks
73 Everett

That's the ideal formula for 1 wavelength in free space.

The "1005/MHz feet" loop formula is about 2% longer than 1 wavelength. The metric equivalent would be about 306/MHz meters.

Andy

Hmm. Not really; not added INTO the loop.

> To my present understanding, the standing wave pattern around the loop
> must continue down each leg of the feeder which is therefore an integral
> part of the loop (but with radiation cancelled out).

Yeah, I don't think that's true. There really is a boundary between the loop and what feeds it.

Remember that if a transmission line is matched, then its length cannot be measured, or "felt", by "looking into" the end. It appears identical to an infinitely long line ... or to a resistor equal to the characteristic impedance Zo. So connecting a 20 meter long, 450 ohm balanced line is identical to connecting a 450 ohm resistor, to the same point. Also identical to connecting a 10000 meter balanced line.

The standing wave pattern on the antenna generally does not continue down the feedline. The presence of standing waves on the feedline depends on the impedance match at the feedline/antenna boundary. There could be no standing waves on the feedline ... even though they are there on the antenna.

It is the same as the feeder line connected to a dipole antenna, or a vertical. Neither one makes the antenna electrically longer.

> If the loop and feeder each contain 40 metres of wire, is the combined
> resonant frequency based upon 80 metres of wire, even though 50% of it

No, sorry.

> Taking this further, how reasonable is it to drop a few metres of window
> line, with its ends shorted, from some point in the loop and expect the
> loop to perform as if its length had been increased by double the length
> of the drop?

Now this is something that actually does do something. The shorted stub behaves like an inductor (if the stub is less than 1/4 of a wavelength long at the transmitted frequency), and adding an inductor to a loop can make it appear electrically longer. It's just like a loading coil in a too-short vertical. You have to be a little careful with a loop antenna, because it does matter where in the loop you insert the stub (e.g., not at the current null points in the loop).

I am not sure if it behaves longer by twice the length of the stub. I suspect it goes by some other formula.

All I can say is, it's a concept I have read about, but don't know very much about. If I remember correctly, ON4UN talks about it in his book in the chapter on loops.

And it might confound things for using the loop on higher frequency harmonics.

Sometimes it helps to achieve resonance as near to the antenna itself, so that you don't have a poor SWR on the feeder line, adding to loss.

Thank you for taking the trouble to explain this so clearly Andy. Your answers certainly make sense.

I guess that as the conductors in a ladder line feeder become further apart, there comes a point at which radiation will no longer cancel and it then starts to become an extension to the loop rather than a feeder.

Greetings all, Just thought re 450ohm line extending the output termination of a loop. If you consider the line as separate from the loop, the line possesses both inductance and most of all capacitance the parallel wires acting as the plates of a capacitor in parallel with, and tuning the loop hence a lower frequency. Theory is one thing, practice another. I hope this confuses the issue even more Hi Hi. Regards to all Max vk2tti.

Yes, I think that is true. But the way in which it becomes an extension to the loop may be complicated.

With normal ladder line, you get near-cancellation. It is not perfect cancellation, but it is so close, that you can pretty much ignore the small amount that does radiate. As you separate the conductors, the cancellation probably becomes less perfect. But separating the wires also changes the impedance, and changes the electric and magnetic fields surrounding the wires, so it might be more complicated than just saying that it "radiates more."

Some powerful radio stations still use open wire feeders to their antennas. For high power radio stations, the wire separation needs to be moderately large (a foot or more), so that arcing doesn't happen between the wires, on account of the high voltages required for megawatt power levels. Some stations even use multiple wires arranged in a kind of open coaxial arrangement, with one wire (or a close grouping of wires) as the center conductor, surrounded by a "cage" of a half dozen or more wires acting as the coax shield. Looking at it, it's amazing to think that it actually works, and it works quite well.

Andy

Thanks yet again Andy.

My horizontal quad loop is used multi-band. It is fed by about 10m of 450 ohm windowline, via a 4:1 balun (at rig) and an ATU but, due to limited available space, I cannot get a full 40m loop up in a reasonable shape - 32m is my max and that is all I am usiing right now. It is on 4 fibreglass poles 8.5m above ground at the east end (house) and 6.5m at the west end. It is corner-fed at the east end.

The internal ATU of my IC-7700 copes well from 6 to 20m but "draws the line" at 40m where the antenna is mainly reactive. I use an external ATU for 40m and it can also tune 80m (Palstar AT2K).

I want to add a 12m "tuck" midway down the north leg of the loop above a wooden out building and propose dropping it in a delta shaped loop with the base being supported about a foot above the roof of the out building.

I realise that the "tuck" will perform nothing like a resonant delta loop at any frequency I will use, but it is a convenient shape and I think it will provide useful radiation.

I would welcome any comments before I commence the work.

Hylton Thompson (g6avl)

> I want to add a 12m "tuck" midway down the north leg of the loop ...

> I would welcome any comments before I commence the work.

As I say, no experience here with that. But according to ON4UN's book, adding inductance at a current null point (1/4 or 3/4 of the way around the loop) doesn't help the SWR.

I wonder if you can 'meander' the loop wire, to fit more wire in to the available real estate. They say it works well with dipoles.

Andy

10067. Loop around a rancher house

Yahoo group: loopantennas (2013 — 2017)

From: Ron Polityka
Topic: 10067 Message: 10067

Hello,

I am new to this list and I have been spending the past few days looking at all the articles and e-mails on-line.

I recently purchased a Johnson Viking 250w Match Box. I would like to place a loop around the rancher house that I live in but not really sure on if it would work. The house measures 70' x 30' with the roof line up about 14' in the front and 20' in the back from the ground. I could extend the length to about 110'. I have 450 ohm ladder line that I can run directly out of the match box to the antenna.

Any suggestions?

Thanks for the band width and any help that I would receive.

73 and Thanks,
Ron Polityka

10068. Mobius Shielded Loop Antenna

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-08-19 18:18:57 UTC
From: Everett
Topic: 10068 Message: 10068

Hi Chris,

I just saw and read your article "Mastering the Art of Shielded Loop Aerials" and of particular interest was the part on the Mobius configured shielded loop. I have been experimenting with shielded loops now for about 2 months, or so. I have been experimenting with a active loop, as apposed to a passive tuned loop. I was never able to get it working to my satisfaction with the standard shielded loop. However, when I started experimenting with the Mobius configuration I started seeming some very good results.

I am working with a 1 meter diameter loop using PEX water pipe for the loop support and I made my own coax using 1/4"OD Poly water pipe used for ice maker water line. The shield was remover from some old RG58 coax and slipped over the plastic tubing. The wire inside of the tubing is 660/46 Litz wire. I put two layers of shrink tubing over the joint at the top to give it some strength where I made the connections of the Litz wire to the shields. At the bottom I connected the two shield ends together and each of the two Litz wires are connected to a M0YAF Broad band amplifier.(Note: the home made coax was slid inside of the PEX water pipe)

I have been comparing the Mobius loop to a active loop that is of the same size using the same M0YAF amp.On 75 meters I get about a 5 S unit higher signal then my standard active loop, using the same broadband amplifier, and about 4 to 5 S units lower noise. One 40 meters the S meter readings are a little lower then the standard active loop, but again the noise floor is lower. On both bands I am able to get good rotational nulls. On 20 meters its performance is a little below the standard active loop. I am seeing equal nulls 180 deg from each other on all bands.

Yesterday I replaced my home made coax with RG11 and it is a little better on the higher bands, now working as well my active loop on signal strengths on 20 meters and it has some directivity when rotating the loop, but blows it away my standard active loop on 75 meters and down, with both signal strength and a lower noise floor. 160 meter has been dead here, so I have not been able to check it out

I also compared the Mobius loop to a tuned loop that I made a while back, that is of the same size (1 meter) and the Mobius loop was a whole lot better in both signal strength and much lower noise on all bands, and blew it away on 75 meters and 40 meters.

So at this point I know that it works well from about 200 KHz to 20 MHz. The band has been crap above 20 MHz, so I just don't know how it will work above 20 MHz. However, when the 20 MHz and above comes to life I will find out.

On this last Saturday I pick up a 50' roll of 1/2" diameter, 50 ohm Heliax coax for $10, that was my best deal of the day. The shield is copper and the center conductor is copper, about 3/16" in diameter. this will become a RX loop sometime, but I am thinking of something larger than 1 meter and it will be the mobius configuration. If anyone has any ideas on what size,with in reason, don't hold back.

So my question is have you made any more experiments with the Mobuis project that is mentioned in your article?

Hi Steve,

It is more local man made noise, but some of it is no doubt atmospheric noise. However, if the atmospheric noise is coming from all directions you can't null it out. I am quite impressed with how well it works and there is no tuning, just give it a turn every now and then. For what ever reason, it seams to have more gain and a lower noise floor on 75 and 40 meters that a active loop the same diameter, which is using the same amplifier, but 14 gage wire rather than coax.

Dear Everett,

Thanks for sharing your obsevations. I would suggest that the difference you are seing in loop performace comes down to how well the loops are matched to the ampfiliers and whether you are using a balanced amplifer to cancel out any near E field noise. All the mobius loop is doing is increasing the loops impedance. This could be have been achieved with a transformer.

Some time ago I compared a Mobius loop (1m diam) to a 1m 3/4 tube loop using an ALA1530 Amplifier and a higher impedance low noise FET amplifier. What I found was; below approx. 16MHz both loop types would provide similar performance when taking into consideration the differing loop z to amplifier input z.

Above 16MHz the capacitance of the Mobius loop was too high and thus the gain drops off. Where both loop types have a resonable match to the amplifier the signal and s/n are the same.

If one looks at the two loop types intuatively, both have the same area, so it would be fair to say that they capture the same signal. With the mobuis the deliverable current to the amplifier is 4 x lower because the impedance is 4 x higher. Hence this is why Pixel use a 50 ohm input z amplifier to acheive good results compared to some designs using a near zero input impedance. The basic fallacy with using a near zero input z amplifier is that a loop is not a low z current source, but a current source with a series reactance. It is this rising reactance verses frequency which dominates the loss in a broadband loop antenna, hence the need to provide a reasonable loop/amplifier match.

FB Everett...I'm surprised to hear that the atmospherics are lower as this 'noise' is usually treated as a signal, unlike some forms of near-field noise. When I rebuilt my 10' active loop, I had consdered doing a Mobius strip but then talked myself out of it as I reasoned that the theoretical doubling of output signal voltage might cause some undesired affects on the preamp's front end as I live less than a mile from the 'AP' ndb on 378 KHz. As well, it seemed to me that by physically connecting the shield to the inner element of the loop, that the 'shielded' loop would simply become a two-turn (unshielded) loop. Your results are of particular interest and I may yet do some further experimenting with the next re-build should the 10 footer eventually come down in one of our winter storms.

If you have not seen it before, the details of my LF shielded system are here:

Hello Andy

Your comment that the loop is a current source with a series reactance is interesting.

My understanding, is that a small loop can be considered as a voltage source in series with the inductance of the loop, the ohmic losses, and the negligle radiation resistance. For a given field strength, the voltage output is proportional to frequency. The equivalent current source has an output which is proportional to field strength only, and has a shunt, not series, inductance.

What am I missing?

I'm not surprised at the results you've seen. With twice the output voltage and four times the terminal impedance, your improved S readings are right on track.

No, I haven't pursued the Mobius Shielded Loop any further. I do want to use it in an experiment for an indoor antenna with varaactor tuning and a tunnel diode negative resistance amplifier/Q-multiplier.

I was looking at loops as being voltage sources with series reactances until I came across a paper that look at them as being current sources with shunt reactances, and it made sense as a loop in a magnetic field generates a current to the load that is proportional to the loop diameter and the signal frequency. That ptomted me to design my wideband loop amplifier with a very low input impedance rather than trying to match the loop reactance over a wide band.

Hi Andrew,

Thank you for your comments and you input. I tried several different hook ups with the standard shielded loop configuration and even tried a matching transformer using one of the 73 mix binocular cores, with several different ratios, but was never able to get it to work just right. I could not get the loop balanced correctly, as my 180 nulls were no where the same. Maybe I just did not come up with the correct combination.

However, with the Mobius configuration it worked from the get go, with the M0YAF amp, of which I built 4 of them. I also tried the LZ1AQ broadband amp, but it did not work very well on any of the shielded loop configurations, but did okay on the standard 14 gage wire loop.

Your observation on the lower performance above about 16 MHz is very similar to what I am seeing, but as I have moved up from first, from RG58, then to my home made coax and now to the RG11, I am seeing improvement. The RG 58 has a capacitance of around 30 pf per foot, I did not measure my home made coax and the RG11 runs about 20 pf per foot, so again in your remarks on the capacitance maybe what is degrading my top end performance.

Hello Again Steve,

Yes I did look at your site and had seen it before, that is quite a loop that you have. I also noticed all of of your projects and old radio/electronic collectable's, very nice.

I just did some rechecking on 2 local AM radio stations, using the Mobius Loop connected to the M0YAO broadband loop, using a Icom R 75 receiver. One station at 690 KHz gave a S meter reading of 20/9, I was able to null it to S9. The other station was 30/9 and I was able to null it to 10/9. So both stations were nulled by 20 S units, it does not seem correct, but that is 120 dB. The nulls were identical 180 deg from each other.

However, as I go up in frequency the nulls become of a lesser magnitude (more sky wave and less ground wave). Also the lower noise floor is more noticeable on the lower bands. What I mean is when switching back and forth from the active 1 meter wire loop to the active 1 meter mobius loop is that I see a wider spread between the ambient noise, lower S meter readings and higher S meter readings with signal, which is easy to see on 75 meters, but much more difficult to see on MW BCB, all though I am sure it is same there also.

Before you make any changes try experimenting with a smaller loop, like maybe a 1 meter, to see if you see what I am seeing. I have not done the kind of comparison that Andy did, comparing it to a standard Shielded loop, as I only compared mine to a active wire loop and a tuned wire loop.

Hi John,

What I believe is happening; the H Field induces a current into loop, this current is not frequency related. However, as the loop has a rising series impedance with frequency the loops terminal voltage is the product the induce current x the impedance. Hence we see that the Vout is proportional to frequency.

This issue of the loops series reactance impeding the current is discussed in a GB patent for the Liniplex loop manufactured by Phase Track in the early nineties. I can't find my copy of this patent. A search for patents by Charles Edward Forster my find it. The Liniplex loop used multiple loops in parallel to reduce the series reactance from impeding the current to the amplifier.

Getting back to the real issue here, we have a loop with output z that is frequency dependant, therefore optimum power transfer to the amplifier will only happen when the amplifier input z matches the loop.

Kind regards

Andrew

In general, any voltage source with series impedance can be converted to an exactly equivalent current source with parallel impedance at the same frequency. The only constraint is that there must be no non-linear devices such as diodes in the the circuit. See Thevenin's and Norton's theorems.

John wrote on August 19,

Your comment that the loop is a current source with a series reactance is interesting.

My understanding, is that a small loop can be considered as a voltage source in series with the inductance of the loop, the ohmic losses, and the negligle radiation resistance. For a given field strength, the voltage output is proportional to frequency. The equivalent current source has an output which is proportional to field strength only, and has a shunt, not series, inductance.

What am I missing?

Tnx and 73

John KC0G

Hi John,

What I believe is happening; the H Field induces a current into loop, this current is not frequency related. However, as the loop has a rising series impedance with frequency the loops terminal voltage is the product the induce current x the impedance. Hence we see that the Vout is proportional to frequency.

This issue of the loops series reactance impeding the current is discussed in a GB patent for the Liniplex loop manufactured by Phase Track in the early nineties. I can't find my copy of this patent. A search for patents by Charles Edward Forster my find it. The Liniplex loop used multiple loops in parallel to reduce the series reactance from impeding the current to the amplifier.

Getting back to the real issue here, we have a loop with output z that is frequency dependant, therefore optimum power transfer to the amplifier will only happen when the amplifier input z matches the loop.

Kind regards

Andrew

John and Andrew are both correct.

If modeled as a voltage source in series with inductance, you will find the output voltage into a resistive load is independent of frequency above a certain threshold, just as with the parallel current source model.

This is because the loop voltage source EMF increases linearly with frequency at 6 dB/octave (induced voltage is proportional to rate of change of the magnetic flux, so when you differentiate the sin(wt) the flux rate of change becomes -w*cos(wt)) and voltage divider formed by the loop's inductive reactance (which doubles per octave) in series with the amplifier input resistance decreases the signal at the amplifier input at the same 6 dB/octave if the frequency is sufficiently high such that the amplifier input impedance is much less than the inductive reactance of the loop. In other words, the 6 dB/octave rising voltage output is canceled by the -6 dB/octave voltage divider effect and the net voltage input into the loop amplifier is constant with frequency.

This series model predicts the same behavior as a parallel current source, so either may be used provided you take care to get the maths correct.

The simplistic -6 dB/octave LR voltage divider assumes, as mentioned earlier, that the loop's inductive reactance is large compared with the input impedance of the amplifier.

Hello Chris et al

The idea of using a low impedance amplifier for a loop antenna is not new.
I have just dug out my copy of "H.F. active antenna performance
requirements and realization", by B.M. Sosin, published in "Communication and
Broadcasting", Summer 1976. Sosin was at one time Chief Scientist at one of the
Marconi companies in the UK.

Sosin discusses how a low-impedance amplifier gives near optimal
amplification over the H.F. frequencies. His assumptions, ie 10dB receiver noise
figure, 3 dB noise degradation, low noise areas at quiet times, lead to an
antenna factor of -2dB, ie a field strength of 0.8V/m is required for 1 Volt
output into 50 ohms.

Sosin goes on to say that only the very best receiving systems would be
affected by the noise degradation, and then by a small amount. In those cases
the amplifier gain could be increased by 3 to 8 dB, or an additional low
noise, low intermodulation products used.

Sosin references a paper by Callendar on wideband loop arrays from 1972.

Ron,
There is no reason not to try this. What frequencies are you interested in? How much power will you run?
With the loop around the house, you and your family are inside the loop, so be aware of the field inside it. Also note that your house probably could cause some sort of electrical interference being inside the loop. Try it and see.

With a 20 foot drop in the back, I would also look at a quad or delta loop if you have trees in your back yard. If you are already up on the ladder, install some eye bolts and pulleys for future experiments.

My rather low delta loop for 40 meters works well on 40, 20, 17 and 15 using my Dentron tuner.

Good luck,
Sal

John,

Ref, to my earlier post concerning the GB Patent for the Liniplex loop. The UK Patent Application no. is GB 2 235 337 A Inventor is Edward Charles Forster. It discusses the problem of the loops series inductance limiting the current to load. In the case of this patent the load is a common base amplifier.

I am fairly new to this group and have been somewhat intrigued by the Mobius loop antenna. Is there any place on the web that describes the construction of the antenna? More specifically I am interested in the VLF/LF arena but I can't seem to locate any links that discuss this.

Hi Sal,

I operate QRP 99% of the time on all the HF bands. I do have a Butternut HF9V in the back yard with 120 radials, Carolina Windom and a TA33Jr beam so if the loop does not work. I do have one tall pine tree on the property.

Going to set it up using PVC at first just to see if the antenna will work. Never know until one tries.

Hello
I am thinking of replacing my single wire loop with a Mobius loop. I looked at several diagrams, including the one in Rev 0.pdf. Most show the shield as not grounded, but the one in Rev0.pdf shows the shield as being grounded at the feedpoint. I don't get this. I can see where the 2 center conductors go to the input of my balanced amp, but if I ground the shield it becomes a dead short to the feedline coax.
I am thinking of using coax to form the loop, snaking it inside a flexible PVC conduit. Thats what I do now with a single wire. I suppose the shieled continuity must be maintained where I cut the coax to bring the two center wires out to the amp? But grounding?
Thanks a bunch!
Jim

It is no more than a dead short, than a loop antenna is a short on the feedline. And yet we know loop antennas work. The "short" is only at DC.

Think of it as a balanced loop antenna where the center-tap of the loop is grounded.

Andy

Topic: 10089 Message: 10098

Hello
Using a balanced amp as I do, the loop is not a direct short to ground at DC. The shield of the feedline is not involved in the loop itself. What confused me was in the Mobius design where the feedline is indeed shorted to the center conductor, which is fine until you also connect it to the feedline shield. Everett cleared that up nicely with his diagram he sent me.
I understand that many antenna designs use matching transformers and such that provide a direct DC path to ground but at RF it not a problem. Not so with a 3 foot diameter loop at VLF or even at 30 Mhz.
All good stuff. Great group here.

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

10103. Re: Mobius Shielded Loop Antenna

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-09-01 11:43:28 UTC
From: hmaxim2000us
Topic: 10068 Message: 10103

Hello Group
I just wanted to update you on the Mobius loop as described by Everett N8CNP . I finally got my RG/11 although it turned out to be a cable with aluminum shielding and some kind of lubricant between the shield and the jacket a real mess to work with. I used it anyway.
So I find that it performs much better than a single turn loop. In fact it equals or outperforms my reference antenna which is an 88 foot twinlead fed inverted Vee at 45 feet. But only in the evening. During the day the loop is almost useless. Have not figured that out yet.
One other thing I was hoping you might be able answer. The loop performance drops off considerably by the time I get to 40 meters. On 30 meters it is nearly deaf.
I am thinking there is a problem with my amp. Do you think T1 should be adjusted? Maybe I am not coupling enough high frequency voltage from T1? I was thinking maybe 15 turns is too much? Also, can I use a F T50 core, and if so, how would this effect the number of turns?
What do you think about the transistors? I get superb performance from 100 khz up to around 4 or 5 Mhz, but after that it really takes a dive. I have a pair of 2n5109's but have not installed them yet. Do you think it would be better than the 2n3904's I use now?
Jim
K2TL

Date: 2013-09-10 08:54:45 UTC
From: <lz1aq@...>
Topic: 10105 Message: 10105

Hello,

I have made some more precise experiments to compare different wideband small magnetic loops working in short circuit mode (the active amplifier is with very low input impedance) : "Experimental Comparison of Small Wideband Magnetic Loops"

http://www.lz1aq.signacor.com/docs/experimental-comparison-v10.pdf

This article is based on previous one: "Wideband Active Small Magnetic Loop Antenna"

http://www.lz1aq.signacor.com/docs/wsml/wideband-active-sm-loop-antenna.htm

There is also a spreadsheet to calculate loop parameters:
http://www.lz1aq.signacor.com/docs/w-loop-calc-v10.xls

From: vbifyz
Topic: 10105 Message: 10106

Hi Chavdar,

Thank you for sharing these very interesting results.
There is one more characteristic that is very important for loop antennas: null depth. It is especially interesting for those of us who are not in a quiet rural location.
Did you try to measure it?
I guess it is defined more by the amplifier common mode rejection ratio, but should be some function of the loop geometry as well.

73, Mike VE3YXA

10107. RE: Re: Experimental Comparison of Small Wideband Magnetic Loops

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-09-11 11:26:50 UTC
From: <lz1aq@...>
Topic: 10105 Message: 10107

Hello Mike,
- A good loop balance (high common mode rejection) is essential in order to reach high null depth. Most often if the loop has different null depths between its two sides the main reason is the poor common mode rejection
- I have not measured carefully the loop null depth because it is very unstable below 20 dB level. I think that one of the reasons is the polarization of the incoming wave. Model simulations show the small loop above real ground has significant horizontal polarization component rotated at 90 deg. to the vertical component. The small loop has very deep null for vertically polarized waves but if the polarization of the wave is tilted slightly there will be the effect of reducing the null since in this direction the horizontal component of the loop pattern has its maximum. So to null completely the source you should have to tilt slightly the loop.
- Model simulations show that in free space crossed coplanar loops have very weak horizontal component – almost null. But above real ground the horizontal component is almost the same as in the ordinary single loop.
- My experiments show that 20 dB rejections is the normal limit for loop rejection. If you reach 20 dB rejection from both sides of the loop that means your loop is working properly. By careful adjustment the man can gain some more dB but that is all. You might reach a rejection above 30 dB but the null will be unstable and will change with the weather conditions, loop tilt due to wind etc.

From: Tom
Topic: 10108 Message: 10108

HI Guys
Could some one explain to me how the Alex Loop or Alex arrived at the small diameter (I am not sure of the exact size)of his loop to be able to run 40m to 10m as I would have thought 7 to 28 would have been much bigger in Dia.
Dose this have something to do with the fact it is designed for QRP?
Thanks for any replies.
Tom

It is 1/5 the length of the big loop.

Hi, everybody!

I have designed PCB to build my own LZ1AQ amplifier at home. I want to share CAD project with comunity - to open it you need to download and install DipTrace program (http://www.diptrace.com/?en=1).

Best regards,
Pavel

It's a compromise antenna on 40m with very low efficiency.That does not mean it won't work! It just theoretically won't work as well as a loop of the proper size for 40m. Lots of folks report very good results using loops smaller than optimum size. But keep in mind under the right conditions it's actually pretty amazing how little power is needed for successful QSOs so efficiency is not always of paramount importance. Alex can better answer how he arrived at the 3 ft diameter but I always figured it was because that's simply a good size for a portable antenna. Regarding why the antenna is for QRP that's a function of the coax used for the main loop and the small air variable cap that's employed, not the fact that it's small diameter.

Kraig,

The reviews point to the Wellbrook being better than the Pixel. I have not tried the Pixel but I do have 3 ALA1530s and they are very good. Pretty much bombproof, low noise, and very good nulls. The latest incarnation of the 1530 is the best yet and you can always upgrade it later to the Imperium version that has more gain and better intermod performance.

I lost my house end tall pine tree, supporter of LW's, Zepp fed, TTFD, etc, several years ago. I gathered my sheckles and that winter found me taking a chance on a USA-made Pixel Pro-1A. It's upgrade to 1B, changing the loop of it's modular construction, is pending - I just hate to replace something that works so well. It was mounted on a five foot TV mast section which was held by an eave mount mounted to my back deck's skirt. The loop's center was maybe eight feet at most off the ground and eleven feet from the back of my house and rotated for minimum noise pickup. In my 36.5 yr of living there, only the TTFD was as quiet - and then only over a narrow frequency range, which didn't include MW as the TTFD signal levels dropped appreciably there. I used my old loggings and my Drake R8 for comparison, switching to my new Palstar R30A in a minimization/simplification attempt.

Jan 2012 found an F4 tornado hitting my neighbors a block away. I lost huge limbs, deck furniture, wind chimes, and bird houses & feeders - but the Pixel PRO-1A was fine. We bought a 'garden home' in an area with an HOA that doesn't permit outside aerials, save a DIRECTV antenna mounted on the backside of the steep roof in July. The floored walk-in attic and CATV wiring made me get a Channel Master tripod TV mast mount and bring the Pixel loop antenna - on it's five foot mast - into the attic. I disconnected the RG-6 up in the attic feeding the CATV jack behind my desk, added six feet of RG-6 to the Pixel's amp and aligned the loop to null the nearby HVAC unit. It would be nearly two weeks before I would find the power inserter and wall wart for the Pixel, although I found my complete set of Magne's PBWBR immediately. Moving is an experience after so long. The result was even better than at my old home! Stronger signals - even local MW stations produced no discernible IM or CM, perhaps as much a testimony to the receivers' designs as to the antenna's! Still, I think the Pixel is a great antenna - and would rather have it over the Wellbrook. Either is a pricey decision.

John

Hi John & all,

I purchased a Pixel Pro-1A in January and could compare it to my 5 Wellbrook loops (ALA1530, ALA100, ALA100M, AVA100, LA1010).
In the competition, the Wellbrook loops always were the best ones, especially in the VLF and NDB band.
I sold it. You understand why !
Here is a very comprehensive test from Guy Atkins between the PIXEL and the ALA1530 loops.
http://tinyurl.com/qj343fz
I fully agree with his conclusions.

Dominique

Kraig,

Assuming that the MW tx is 50kW and transmitting at 1MHz, and the environment is suburban then you will get nearly 0dbm into your receiver with a loop. That is a very big signal.

The Imperium second order intermods are 90dBm and the thirds are spec'd at 55dbm. Even a modern rtcvr such as the Kenwood 990 with the preamp off has 3rds at ~35dBm so the receiver will be the limiting factor not the Wellbrook loop. I don't know what rx you are using so difficult to say whether it will cause problems. But at least the loop will allow you to put the MW tx in the null and that will reduce the signal by up to 30dB.

Because the loop and its amplifier are more linear than the receiver, if you do have problems you can simply switch in the attenuator in the receiver.

Kevin,

Working on the assumption of a 50kW Tx the F/S will be approx. 114dBuV/m at 1MHz for a 4km distance. The Imperium uses the same loop as the ALA1530 with an AF of about 5dB. Also the Antenna Interface amplifier will add another 9dB of gain. So the loop will be pushing +12dBm. This is far too high to ensure IMD free reception even with Rx attenuation.

Kraig, did contact me a few days ago and I suggested that he should consider the ALA1530LF as this lower MW IMD.

A lower cost option of using the ALA100LN or the ALA100M with the loop size tailored for IMD free reception is worth considering.

Kind regards

Andrew Ikin

Hello Dominique, etc,

I met Guy many years ago while we both worked on Proceedings, etc. I respect his opinion even if I don't always agree with it. Jack Smith, owner/founder of Clifton Labs, did a bit more rigorous comparison of a Pro-1B and a 1530L and his results are published on the Pixelsatradio.com site. His findings were that the Pro-1B bested the 1530L nearly 2/3 of the time averaging over 3db better s/n ratio, with the Wellbrook's better performance datums not quite as high. To put that in perspective, the wrong headphones, earwax buildup, a touch of tinnitus, etc, even distorted audio stages, can make a 3 db s/n ratio difference inconsequential.

Often, reviewers have 'a dog in the hunt' - a vested interest - which taints their objectivity. That could be the case here - or not. Guy's review is on Wellbrook's site - Jack Smith's is on the Pixel site - and he is the EE that designed their preamp! So, they should be taken with a grain of salt. Dominique, I don't doubt you got better signals on VLF - NDB's - your Wellbrooks are clearly better (My Pro-1A gives an S7 for 25W NDB 'BH' some 24 miles from here!) below the MW BCB - gain goes to zilch by 100 kHz. MW and SW - to 16 mb -on my Pro-1A are super - the combo of it, the Palstar and it's Colins mech (Okay, torsional!) filter, and a decent speaker makes program listening fun again - or would if there were still SWBC stations!

The modular construction made the improved preamp Pro-1 become the 1A, while an improved loop made the 1B. Upgrades are easy with such modular construction - impossible with sealed/potted preamps made into the antenna. Wellbrook's continued improvements means a new antenna! Oddly, price is important, too - and the Pro-1B is now $500! Oops....

John Wrote on Sept. 14.

"The modular construction made the improved preamp Pro-1 become the 1A, while an improved loop made the 1B. Upgrades are easy with such modular construction - impossible with sealed/potted preamps made into the antenna. Wellbrook's continued improvements means a new antenna! Oddly, price is important, too - and the Pro-1B is now $500! Oops...."

John, Wellbrook's loop amplifier can be replaced at a reasonable price; much lower than Pixel's price of $200.00 that a fellow group member mentioned a while ago.

Regards

Andrew

Wow - I heard that the Wellbrook's pre-amp requires surgery to get it out of the antenna and even then it is potted, making further dissection impossible. I have no first hand knowledge of this - if someone does, please report in!

Hi John & all,

I purchased a Pixel Pro-1A in January and could compare it to my 6 Wellbrook loops (ALA1530 (2x), ALA100, ALA100M, AVA100, LFL1010).
As I have a very uncomfortable pest close to my QTH (12km / bat. 7mi) i.e. a LORAN-C transmitter (LESSAY/Normandy) which sends 250kW on 100kHz from a 250m high tower 24 hours a day, you can imagine that the tests are quite hard to pass for the antennas whatever they are!
I can say the Wellbrook loops always were the best ones in terms of S/N and sensivity, not only in the VLF and NDB band !
I sold the Pixel Pro-1A. You understand why !

Here is a very comprehensive test from Guy Atkins between the PIXEL and the ALA1530 loops.
http://tinyurl.com/qj343fz

I fully agree with his conclusions.
Have a nice day

Dominique
Normandy, France

I lost my house end tall pine tree, supporter of LW's, Zepp fed, TTFD, etc, several years ago. I gathered my sheckles and that winter found me taking a chance on a USA-made Pixel Pro-1A. It's upgrade to 1B, changing the loop of it's modular construction, is pending - I just hate to replace something that works so well. It was mounted on a five foot TV mast section which was held by an eave mount mounted to my back deck's skirt. The loop's center was maybe eight feet at most off the ground and eleven feet from the back of my house and rotated for minimum noise pickup. In my 36.5 yr of living there, only the TTFD was as quiet - and then only over a narrow frequency range, which didn't include MW as the TTFD signal levels dropped appreciably there. I used my old loggings and my Drake R8 for comparison, switching to my new Palstar R30A in a minimization/simplification attempt.

Jan 2012 found an F4 tornado hitting my neighbors a block away. I lost huge limbs, deck furniture, wind chimes, and bird houses & feeders - but the Pixel PRO-1A was fine. We bought a 'garden home' in an area with an HOA that doesn't permit outside aerials, save a DIRECTV antenna mounted on the backside of the steep roof in July. The floored walk-in attic and CATV wiring made me get a Channel Master tripod TV mast mount and bring the Pixel

loop antenna - on it's five foot mast - into the attic. I disconnected the RG-6 up in the attic feeding the CATV jack behind my desk, added six feet of RG-6 to the Pixel's amp and aligned the loop to null the nearby HVAC unit. It would be nearly two weeks before I would find the power inserter and wall wart for the Pixel, although I found my complete set of Magne's PBWBR immediately. Moving is an experience after so long. The result was even better than at my old home! Stronger signals - even local MW stations produced no discernible IM or CM, perhaps as much a testimony to the receivers' designs as to the antenna's! Still, I think the Pixel is a great antenna - and would rather have it over the Wellbrook. Either is a pricey decision.

John

John,

The replacement amp. is designed to slot into the loop once the old amp has been cut off. This option is normally offered to customers where the shipping cost for a new loop is too high.

Kind regards

Andrew

Andrew,

I assumed suburban path conditions, if I assume the same sort of ground conductivity found in my locale then I also get around the 12dBm level. This is a 2.5volt peak to peak signal in a 50 ohm circuit so the back to back protection diodes, if fitted, will be working overtime, so a definite no no. I would imagine the bandswitching diodes would be having a hard time too.

I understand that the Pixel has a high gain amp and so I think that there would be issues with this model when using it so close to the MW tx.

□

Kevin,

Working on the assumption of a 50kW Tx the F/S will be approx. 114dBuV/m at 1MHz for a 4km distance. The Imperium uses the same loop as the ALA1530 with an AF of about 5dB. Also the Antenna Interface amplifier will add another 9dB of gain. So the loop will be pushing +12dBm. This is far too high to ensure IMD free reception even with Rx attenuation.

Kraig, did contact me a few days ago and I suggested that he should consider the ALA1530LF as this lower MW IMD.

A lower cost option of using the ALA100LN or the ALA100M with the loop size tailored for IMD free reception is worth considering.

Kind regards

Andrew Ikin

□

Kraig,

Assuming that the MW tx is 50kW and transmitting at 1MHz, and the environment is suburban then you will get nearly 0dbm into your receiver with a loop. That is a very big signal.

The Imperium second order intermods are 90dBm and the thirds are spec'd at 55dbm. Even a modern rtcvr such as the Kenwood 990 with the preamp off has 3rds at ~35dBm so the receiver will be the limiting factor not the Wellbrook loop. I don't know what rx you are using so difficult to say whether it will cause problems. But at least the loop will allow you to put the MW tx in the null and that will reduce the signal by up to 30dB.

Because the loop and its amplifier are more linear than the receiver, if you do have problems you can simply switch in the attenuator in the receiver.

Kraig,

The reviews point to the Wellbrook being better than the Pixel. I have not tried the Pixel but I do have 3 ALA1530s and they are very good. Pretty much bombproof, low noise, and very good nulls. The latest incarnation of the 1530 is the best yet and you can always upgrade it later to the Imperium version that has more gain and better intermod performance.

John,

I recently replaced a 1530 head amp on my vintage 1999 Wellbrook loop. I just took the screws out and twisted the old head amp until it became free. The preferred method is to use a junior hacksaw and remove it that way. You might find some old potting compound in the ends of the loop but this just comes out with a bit of effort with a screwdriver. The new amp is already potted, no need to mess around.

Fitting the new one is simple, the loop ends fit snugly over the tubes on the new head amp. You can then leave it as a friction fit or you can use some self tappers to attach it. I paid 60 GBP shipped in the UK, approx $90.

I have posted a picture of my replacement head amp in the photos section.

My Pro-1A came with a trio of inline (F/F male & female connectors) 6db & 10db attenuator pads for possible use under such conditions as you described. Although they are not listed in the current Pixel site instruction sheet for the Pro-1B, they are clearly viewable in the poly bag of accessories in their picture.

I don't think you can go wrong with either loop - there are just too many 'happy campers' using them. Kevin, you may just benefit by using RG-6 Quad cable with F connectors and BNC/UHF to F connector adapters to lessen cable pickup of that MW powerhouse at least for the long run to your loop, should you choose the Wellbrook. Even my Lowe HF-150, an aluminum brick with a radio in it, picked up PC hash via a six foot made up BNC/BNC(molded connectors) & generic RG-58, admittedly run behind my LCD monitor. A switch to RG-6 Quad eliminated that RFI. The Palstar R30A (The Lowe was on top of it!) still had some RFI, but it was next to the monitor. It has sub-par shielding itself, cured here by putting it across the room on an empty desk.

I had a 50kw 850 kHz daytimer with multiple towers a couple of miles from my previous home - and I was in a major near-field lobe. My Pixel loop was up there for 2.5 yr with no problems. I am now another couple of miles removed from it - and with another mountain between us as well. Still, the R30A's S-meter gives it a 40+ db/S9 - and splatter from 830-870 kHz in the daytime, but I recall my old Collins R390A having more problems with that station using my old 165 foot lw. I am happy with the loop's pickup as-is or I'd go into the attic and null that powerhouse! Choices...

Best,

John

Kevin,

No - they go between the power inserter and the receiver. They can be used in series, but I don't recall if there are two 6db and one 10db pad or vice versa. I haven't found them yet - or lots of things - since the move. More boxes...

Hello, Dominique!

First - did you buy your Pro-1A used in January? The Pro-1B has been out now for over two years. Perhaps your Pixel loop was defective? No matter - I would choose the less expensive, in initial equipment and shipping costs, Wellbrook, too if I lived in Europe! In light of the Pixel's now 500 U$D cost - plus shipping - the Wellbrook would look good to me, too - if I wasn't happy with my Pixel.

Secondly... folks still use LORAN-C?? Even cellphones and cameras now have GPS receivers! Wow!! I guess it's like the aeronautical NDB's - there are still a few of them around. Enjoy your receiving.

Best
John

Topic: 10113 Message: 10135

Hello John

Where have you been hiding :-)
I'm aware that the US have switched Loran C off, but over here in Europe
we're implementing an Enhanced Loran (e-Loran) system
Being totally dependent on GPS has not got to be a good idea.

http://en.wikipedia.org/wiki/LORAN#United_Kingdom_eLORAN_implementation

Regards

Tracey

Hi John,

Sorry, I was wrong abt. the Pixel type, it was the Pro-1B !
It was a brand new stuff, I'm sure abt that !

Concerning the price difference between the Pixel and the Wellbrook antennas, bear in mind that a member of the Loop antennas Group said Pixel wanted 200 bucks for a new amplifier while a new one for an ALA1530 costs approx. only" 90$ (including shipping to the US) !

As for the LORAN-C, I can imagine that you as a North-American are a bit puzzled and don't understand that it's still in use in Europe as we all use it with our cellphones, our cameras and our cars.
The reason is that Europe is entirely dependent of the US concerning the GPS system. If the US administration for any reason turns off the GPS'tap or even if the system gets failing, Europe will be left high and dry !!!
As long as Europe doesn't have its own global satellite navigation system (called Galileo), the LORAN-C system will be used because it's a matter of security for aircrafts and ships navigation.
More infos there:
http://www.esa.int/Our_Activities/Navigation/The_future_-_Galileo/Why_Europe_needs_Galileo

Hope it helps

Have a nice day

Dominique
Normandy, France

Hello, Dominique!

First - did you buy your Pro-1A used in January? The Pro-1B has been out now for over two years. Perhaps your Pixel loop was defective? No matter - I would choose the less expensive, in initial equipment and shipping costs, Wellbrook, too if I lived in Europe! In light of the Pixel's now 500 U$D cost - plus shipping - the Wellbrook would look good to me, too - if I wasn't happy with my Pixel.

Secondly... folks still use LORAN-C?? Even cellphones and cameras now have GPS receivers! Wow!! I guess it's like the aeronautical NDB's - there are still a few of them around. Enjoy your receiving.

Best

Can one purchase just the ALA1530LF headamp from Wellbrook and build their own loop for it? I don't see just the headamp listed on their webpages so I wonder if
someone can buy one special order or do they sell them only as replacements for someone who already has one of their loops? I would need both the headamp and
the matching power inserter. Thanks for any info.

I notice that they made no mention of the Omega system. It was an alternative LF system similar to Loran, and it was worthless. The receivers we had on the USAF C-130s at the time continually broke lock. I don't know if that system even exists any more.

No according to Wiki it was closed down in 1997, although the Russian Alpha system is still active.

Good riddance. My most memorable experience with it was a trip from Nellis AFB to Harrisburg PA. We did not have a navigator with us, so I substituted as I knew how to work most of the position (as well as flight engineer). We went through a cold front over Colorado and the Omega immediately broke lock. I had to use the Doppler drop radar as a backup, and when we got to Harrisburg I was off by just 1/4 mile.

Wish I had taken the opportunity to learn how to use the sextant.

Chris

Kraig,

I looked at the group page as I was not getting all the postings delivered to my email address. I noticed that you had left some details of your local MW tx. Apparently it is only 5kW and has a directional beam so as long as you are not in the wrong direction you will find the signals a lot lower than have been previously advised.

Assuming 5kw radiated in your direction, a frequency of 1460 kHz and the ground conductivity in that area of the US, you should see a field strength of around 65 mV/M or 96dBu. I am not sure what the antenna factor of the Pixel is but the Wellbrook standard 1530 is 5dB, so you will get 36 mV or -16dBm into your receiver. Still a big signal but your rx should be able to handle it, ideally with the preamp switched out.

Kraig,

The reviews point to the Wellbrook being better than the Pixel. I have not tried the Pixel but I do have 3 ALA1530s and they are very good. Pretty much bombproof, low noise, and very good nulls. The latest incarnation of the 1530 is the best yet and you can always upgrade it later to the Imperium version that has more gain and better intermod performance.

They list it in the "see also" section at the bottom.

Loran is mentioned on the Omega page also.

http://en.wikipedia.org/wiki/OMEGA_Navigation_System

"Omega was shut down permanently 30 September 1997."

Kevin,
Thanks. Based on the input I'll probably purchase the Imperium version as I believe my rx will handle any potential overload fro 1460 kHz.

Wish YG would allow me to remove prior comments when I reply so as to avoid a lengthy response.

Kraig,

I did my calculations based on the standard 1530. The Imperium will give you 9dB more signal into your rx. What I did was to get the standard 1530 which comes with the straight through interface unit/power inserter and a while later bought the Imperium interface unit which has the 9dB amplifier built in it. The loop and head amp are identical for both models. I recall Andrew suggested the 1530LF, they are all good.

I guess you can get a good feel for the strength of the 1460k signal from your existing system.

I just asked Pixel for a quote for their loop. Including shipping to the UK it was $600. With import duty and tax this is going to be over $700! Ouch.

10147. Pixel Loop Amplifier Repair Charges

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-09-17 18:38:09 UTC
From: <Jack.Smith@...>
Topic: 10147 Message: 10147

There has been some incorrect information circulated in this group concerning the repair cost for Pixel Pro-1 loop amplifier after the warranty period.

I spoke with Doug Talley at Pixel about the subject and he asked me to pass along Pixel's response to the group.

1) A Pro-1 loop owner can return his amplifier module for repair at a price of $100. A new amplifier board will be installed in the old enclosure and returned to the customer. (I believe a small separate charge is made for return shipping.)

2) The $200 price quoted is for a new loop module, consisting of a loop amplifier board and new enclosure, as might be purchased for an on-the-shelf spare or for some other purpose.

Kevin,
Yes, Andrew suggested the 1530LF. I was planning for the future in case we either move or 1460 kHz leaves the air.

Is it possible to turn on/turn off the 9dB amp built into the Imperium version? If so, then I could turn on or off as needed.

I looked at the group page as I was not getting all the postings delivered to my email address. I noticed that you had left some details of your local MW tx. Apparently it is only 5kW and has a directional beam so as long as you are not in the wrong direction you will find the signals a lot lower than have been previously advised.

Assuming 5kw radiated in your direction, a frequency of 1460 kHz and the ground conductivity in that area of the US, you should see a field strength of around 65 mV/M or 96dBu. I am not sure what the antenna factor of the Pixel is but the Wellbrook standard 1530 is 5dB, so you will get 36 mV or -16dBm into your receiver. Still a big signal but your rx should be able to handle it, ideally with the preamp switched out.

Kevin,
Thanks for the input. I have a local MW station about 2.6 miles from my QTH. Will this local MW station cause problems with the Imperium version?

Kraig,

The reviews point to the Wellbrook being better than the Pixel. I have not tried the Pixel but I do have 3 ALA1530s and they are very good. Pretty much bombproof, low noise, and very good nulls. The latest incarnation of the 1530 is the best yet and you can always upgrade it later to the Imperium version that has more gain and better intermod performance.

Kraig,

The Interface Norton Amplifier is not switchable. But I guess if you use 10dB Rx attenuation; this should be similar as having the loop with a passive Interface. I could free issue a passive interface if you need one. Also I have a couple special Clifton Labs MW filters (switchable) that can be inserted between the Antenna Interface and loop feeder. However, I would have to charge for this.

73

Andrew

Kevin,
Yes, Andrew suggested the 1530LF. I was planning for the future in case we either move or 1460 kHz leaves the air.

Is it possible to turn on/turn off the 9dB amp built into the Imperium version? If so, then I could turn on or off as needed.

73,

Kraig

□
Kraig,

I did my calculations based on the standard 1530. The Imperium will give you 9dB more signal into your rx. What I did was to get the standard 1530 which comes with the straight through interface unit/power inserter and a while later bought the Imperium interface unit which has the 9dB amplifier built in it. The loop and head amp are identical for both models. I recall Andrew suggested the 1530LF, they are all good.

I guess you can get a good feel for the strength of the 1460k signal from your existing system.

I just asked Pixel for a quote for their loop. Including shipping to the UK it was $600. With import duty and tax this is going to be over $700! Ouch.

Subject: [loopantennas] Pixel Loop Amplifier Repair Charges

There has been some incorrect information circulated in this group concerning the repair cost for Pixel Pro-1 loop amplifier after the warranty period.

I spoke with Doug Talley at Pixel about the subject and he asked me to pass along Pixel's response to the group.

1) A Pro-1 loop owner can return his amplifier module for repair at a price of $100. A new amplifier board will be installed in the old enclosure and returned to the customer. (I believe a small separate charge is made for return shipping.)

2) The $200 price quoted is for a new loop module, consisting of a loop amplifier board and new enclosure, as might be purchased for an on-the-shelf spare or for some other purpose.

Thanks Jack,

I understand. The comparison is really between the new Pixel amp at $200 vs the new Wellbrook headamp at $80. The gap widens when you look at the cost for a European buyer as we get hit with VAT and import duty which, with shipping, will push the cost up to something like $275.

Ken - KB7H"

Ken, the L/C circuit would have to provide shunt z of approx. 1 Ohm or less because it is across a loop/Amplifier z of about 12 Ohms at 1420kHz. Also one would have to experiment to see if the loops responce at other frequencies isn't affected. However, Your idea may work with a ALA100 or the ALA100M as these use higher input z amplifiers.

Can I purchase a new Wellbrook amp for $80 even though I am not an owner of a Wellbrook loop? Or is it the price for a loop owner needing a repair? If the former, I should buy a dozen of the amps, bend up a few dollars of aluminum and I have a $100 Wellbrook loop for sale in competition with Wellbrook. (DC power injector would have to be added, of course.)

About 20-25% of my Clifton Laboratories business is international, a large majority of which is to Europe and I know about the problems of those sales. Shipping and VAT are expensive. Fortunately duty is generally not charged in most countries where the goods being imported are for amateur radio use. But 20% VAT will be above the small exemption, which in the UK I recall as being around US$ 20.

On the other hand, goods brought into the US from Europe for personal use are given a reasonable exemption and I've never been charged duty on anything shipped from Europe or China or other countries to me. And the US does not have VAT (yet, although it's proposed every now and then), so other than shipping, anything bought in the UK and shipped to the US comes in without additional charge beyond shipping in nearly every case. And, since UK and European prices are normally stated (by law in most countries as I understand it) as inclusive of VAT, and since VAT is remitted on export sales, it's often cheaper for me to purchase something from Europe and have it shipped to me than it is for a local European customer to buy the same item locally.

The problem in this is how various government set up their tax systems and how it can be tilted to encourage exports and discourage imports. The seller, not to mention the customer, is at the mercy of that system.

I should add that I am asked for a surprisingly large number of Euopean customers to put a false (low) value on the goods or to identify them as "gifts" to avoid VAT. That would put me at risk as it is a false customs declaration and I won't do that.

Jack,

The real ripoff in the VAT system is that it gets charged on top of the product price and the shipping, and at 20% in the UK that is just crazy. Then there is the handling/admin charge from the importer to process the product through customs. The import duty is tiny; sometimes I get hit with it sometimes not. You have to make sure the correct commodity code is plastered all over the shipping container in big writing. If items are dual use customs can decide to hit you with import duty if they feel like it.

Just picked up from another Yahoo group:

"A short video showing the differences between an unbalanced single wire antenna and the ALA1530 loop. The OM uses a currently popular "piece of wire +a step-down transformer in a box" at the connection, better known as 'End-fed' antenna.

The End-fed suffers from severe local noise pick-up, whereas the Wellbrook ALA1530 shows clear reception vs zilt at the popular wire.

Nothing new learned here !"

Hi All...I have a question about tuned magnetic loops. I have constructed a homebrew loop antenna from 1/2 inch copper pipe. The main loop diameter is 40 inches (~1 meter), and the pickup loop diameter is 8 inches (1/5 of the main loop). My question is : What is the feed point impedance of the pickup loop and do I need to use a balun to match to 50 ohm receivers? It works quite well without a balun, but I was wondering if it could be improved with one.

Thanks For Any Help
Nick Rumple

I believe the reason for the 5:1 loop diameter ratio, was to get to the ballpark of a 50 ohm feed impedance. I think it does vary as you change the orientation of the pickup loop, and/or change its shape.

I've seen mention that a 1:1 balun would be best between coax and the pickup loop, but that you can do without one.

An alternative would be to place a resonant parallel circuit in series with the signal path, probably after the preamp or input transformer... This would also introduce some loss but might be fun to experiment with the idea. I remember ages ago building tunable traps for BCB harmonic rejection. They seemed to do the trick then...

☐
Ken wrote on Sept. 18.

<SNIP>

"Couldn't one build a simple series L/C circuit across the loop termination to attenuate the offending TX?

Ken - KB7H"

Ken, the L/C circuit would have to provide shunt z of approx. 1 Ohm or less because it is across a loop/Amplifier z of about 12 Ohms at 1420kHz. Also one would have to experiment to see if the loops responce at other frequencies isn't affected. However, Your idea may work with a ALA100 or the ALA100M as these use higher input z amplifiers.

I think the pickup loop itself can be seen as the secondary winding of a balun (main loop is the primary). Don't see why you would need yet another balun when there is already one. As for the impedance, in my experience 1m main loop + 20cm pickup loop gives me a good SWR on 40m and 30m. Not so good on 20m or 80m. This tells me the impedance changes quite a bit with the band.
For receive only you probably don't care about the precise matching, it will not affect the number of stations you can hear.

That's what I used to think too. But I have read otherwise. And it makes at least some sense that having an unbalanced pickup loop near the main loop upsets the balance in the main loop too, which could mess up the depth of the nulls. That was specifically given as the reason why the pickup loop wants to be kept balanced too. Your magloop will work without the balun, but it may lack the sharp nulls of a well balanced loop.

G'day all. I have ben following the loopantenna saga. I do not use pickup loops anymore. Prefer to use a capacitor to tune the loop and another variable to match the impedance to the radio. What I pick up on the swings I lose on the roundabouts, the loop becomes unbalanced the radiation pattern is distorted and the impedance is sensitive to the size of the Loop. However I am aware of the shortcomings and live with it The old 80/20 rule applies 20% of effort will get a you 80% return but that last 20% return will only be got with another 80% of effort. Regards to all Max VK2TTI

G'day all again. Some more thoughts re main loop/pickup loop thing. If you consider them as a transformer a multi turn (say 10 turns) and a pickup loop (1 turn).Voltage (in the secondary) is reduced by 10 and the current available increased by 10 (to keep P=RI). Impedance transformation is to the square of the turns ratio, assuming a 50 ohm secondary the the primary winding will be 50 x 100= 5000 ohms. A parallel tuned loop exhibits a high impedance. If you assume a 100ohm secondary we get a transformation of a 100 x100= 10,000 ohms (I hope my Maths is right. If we consider a 1 turn loop and pickup the square of 1 is 1 ie no impedance transformation. That is why I gave away pickup loops for single turn loops. Copper pipe is good but expensive, for small loops I prefer aluminum strip, gets an oxide film but can be brushed clean with a brass wire brush. I believe (religion) that an unbalanced pickup will unbalance the system. Regards again, Max VK2TTI.

G'day Tony and all. Thank you for the heads up re G0CWT website have gone straight to it. Very impressive video with the neon tube and the high voltage and the clamp on current measure. My youngest daughter joined the human race and went to uni studdied engineering as a mature age student, now she am be one wiff a first and second class honours to her credit. She came homn one day said " You know Dad when you try to measure something you change it! ". It seems to me that G0CWT has demonstrated that adding an unbalanced pickup loop to a tuned loop alters the theoretical current and voltage distribution expected. I would like to see the same demonstration done without the pickup loop. The problem then becomes how to excite the loop in free space! Still an interesting website. Max VK2TTI.

Tony and all, I am troubled by the repeated reference to the word balun, unless I have read incorrectly, nowhere does G0CWT refer to his transformer feed as a balun! And rightly so, whether or no it affects the balance of the loop I have no way of measuring. In practice it would not matter much, if I can't hear the difference does it matter? Regards to all, Max vk2tti.

From: <leschyna@...>
Topic: 10170 Message: 10170

Hi, I just joined this group and wanted to say hi to all... I am a big fan of loop antennas and in particular Magnetic Loop antennas. I have made many types of transmitting antennas over the 35 years that I have been a radio amateur. My specialty is magneic loop antennas (MagLoop, my brand) and free standing vertical dipoles. I hope to learn and even contribute to this group going forward.

No, the feed point should be very close to 50 ohms that is what the transformer is doing. However, a 1:1 balun does have its place in further limiting the noise picked up by the loop and sent to your RX via common mode.

Hope that helps.

Like the guy said if you want a symmetrical & noise reduction set up the balun would help.
Bur what Thomas has done, is to use a wide band ferrite ring coupler, to give you a 50.Ohm secondary, ensuring optimum power transfer, to your receiver. If you are transmitting, it is worth worrying about, wanting a balun, to remove feeder radiation.Otherwise for listing purposes you will not notice the difference, as most broadcast stations run 10kW or more.

10175. RE: Wellbrook Loop ALA1530

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-09-24 20:09:04 UTC
From: <fm5gb@...>
Topic: 10113 Message: 10175

Hi Todd

I purchased the ALA100LN from Wellbrook which is a low noise preamp ranging from 50 kHz thru 30 MHz. It ships with the power supply and must be fitted with a loop of ur choice (can be a circle, a square or a delta).
Don't make it bigger than a 21 m circumference delta loop or u experience too much signal and possible unwanted products may appear.
I utilize it from VLF thru shortwave, some time as a seperate receiving antenna with the second receiver of my Flex 5000. It has not been damaged yet by the hi power transmitting antennas which are very close to it. Compared to my ALA1530 it bring 10 to 20 dB stronger signals to the receiver but with NO improvement of the signal to noise ratio.
Any way il is interesting to experiment with different loop shapes and sizes.

Best 73's de Phil FM5GB

---In loopantennas@yahoogroups.com, <toddroberts2001@...> wrote:

Can one purchase just the ALA1530LF headamp from Wellbrook and build their

own loop for it? I don't see just the headamp listed on their webpages so I wonder if

someone can buy one special order or do they sell them only as replacements

for someone who already has one of their loops? I would need both the headamp and

the matching power inserter. Thanks for any info.

Guys,
I just deleted "A Practical Approach To Building and Evaluating a Broadband Active Loop Antenna, looking at the Mobius, Conventional Shielded and Wire Loops". It is being replace with a corrected copy. I have also added a part 2 to the original article. In "Part 2" I looked at a home made coax mobius loop and one built out of PEX-AL-PEX water pipe.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1. * Justice AM Loop Antenna (Active)

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

Radio DXing with The Interference Problem
This is great for that annoying problem you have with your loop antenna, and you may think its the loop, think again it could be that messed up street light, next doors dimmer switch, and other something else you can't probably solve with just a loop antenna.

10179. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-10-01 12:38:15 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 10179

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thank you. I noticed the power regulation filtering/decoupling differs from the original schematic. Does the inclusion of protection diodes effect the low-pass filter much?

With a friend I am in the process of building a magnetic unturned active loop of about 1 meter diameter for each of us for general and ham band listening.

I have often seen remarks that these loops perform best at a few meters above ground level.

Has anyone got any experience with the use of this type of antenna on a rooftop.

We have the option of placing this antenna on the flat concrete roof of a flat building of about 30 meters height, any advice?

How would this compare with the positioning of this same antenna on the balcony railing somewhat lower?

I hope someone can fill in the voids in my own experience.

Attachments: 1 described; binary payloads are missing from this source WARC

Consider that ultralight DX listening is mostly done on a tabletop... with enhanced external iron core loop antennas.. I recently received an article about a radial wire antenna literally laid on the ground! Running a long wire for MW listening is a challenge for most. This article blows away the idea that an antenna needs to be elevated. Haven't tried it myself, but I will be soon. a great idea for portable operation. Mind you I am only considering receive mode here. Transmitting antennas is another story.

I would think a loop would operate very well at ground level. I do recall seeing a rather large loop for a radio station in Washington State. The thing had to be 30+ ft high....a rather thick monster sitting on a small mountain top. It was on the ground. on a cement slab. Its in the town of Odessa near the water tower.

I would keep it close to the ground. maybe 6 ft - 10 ft?

Best Regards
Phil

Yes they both differ from LZ1AQ's notes. I wondered if these changes were made to modify the performance of the amplifier.

I have tried both, and I have also asked around for
advice and best practice.
The advice I have been given is that the best location
depends on mainly two things:
1. Frequency of choice
2. Type of local desturbances experienced

Me, being a LW, NDB and MW- buff with lots of local urban electrical disturbances from PSU, TV-sets, etc, I settled for the ground mounted. This gives me the least amount of disturbances going into the loop, because the soil screens a big part of the circumference of the loop, the bottom part. :)
The higher the ferquency you want to cover, the more the loop
benefits from a high altitude. Bear also in mind that loops are
more directional at lower frequencies.
You guys, building two loops, have the golden opportunity. Place
yours in the garden and your buddy's on the roof and try out
best practice for your own needs.
Good luck, and dont forget to build a yourseves good, low noise amps. Loops arent whichcraft by any kind, small antennas generate lesser signals than big, by comparison.

It's not necessary to elevate a magnetic receive loop as the pattern is the same whether at ground level or 30 feet above ground. If you do elevate the receive loop the vertical or near vertical run of coax feedline will pick up noise in the local field which will defeat the S/N improvement that one normally looks for in this type of antenna.

This problem can be pretty much solved by adding coaxial choke BALUNS at the feed point of the receive loop and at the radio shack service entrance. But it's not a fool proof solution.

DL2KQ says you MUST elevate the loop, especially if it is relatively large:
http://dl2kq.de/ant/3-73.htm
Please try to use Google Translator or any other. This is extremely interesting article, written by DL2KQ.
For those who doesn't know: this guy published 6-part Antenna theory book, as well as re-build first the known MMANA modeling SW, then made a new one, GAL-ANA, which is very popular today among antenna manufacturers.
I think that with only limitation -written in Russian- this web site is most comprehensive antenna-related web site today.

Sorry, some addition: one needs to elevate the RX loop in case we are talking about the roof of condos/apartment building. There is definitely no need doing so if you are on the ground.

We moved in July to a 'garden home' some 2.6 miles from my previous home in a community with a strict Home Owner's Association, including no external antennas save a satellite TV dish on the back of the house, and underground utilities. My previously low back deck mounted Pixel PRO-1A loop, fed with RG-6QS, went from outside mounted loop center at 8 ft above the ground and oriented to lessen the powerline/house wiring noise pickup to 22 ft above the slab inside my steeply inclined attic. Noise pickup is far less than the best days at my old home and local MW stations, WWV, R. Australia, etc, are as strong as before on both my Palstar R30A and Icom R75 - just more noise free. I did orient the loop to minimize dimmer noise pickup from the kitchen pot lights, but, as I am the cook, I just leave them off when I want to critically listen.

I moved the loop & amp still connected to a 5 ft mast section - and quickly mounted the mast in a tripod mount resting on the attic's plywood floor. All the way up, I still would have 3-4 ft to the roof's ridge. I ran some RG-6QS to the area over my office where I found RG-6 leads from the two F female panel jacks in my room. It was super easy to feed the loop from behind my desk - thank you thoughtful house designer!

The loop was tried at my old house after I lost my tall trees, longtime long wire supports, and could no longer null the powerline noise. It's great for nulling one source of QRM - like the high tension lines which ran in front of my old house - and resurrected my SWLing hobby. Putting it up from 8 ft to 22+ ft didn't seem to affect the signal strength - the underground services seem much quieter. My advice is to separate the loop from local noise sources and then minimize the pickup of same by rotating the loop. The height over ground shouldn't matter re signal pickup.

Good listening!

John

Cor,

For receive only, I performed some experiments a few years ago with a 2 meter diameter untuned loop consisting of 1/2 inch water copper pipe and minicircuits balun(s) interfacing to the coaxial cable. Cable(75 ohm RG-6 Quad shielding) had large ferrite beads or alternatively, multiturns on large diameter toroids at both ends. Outside of the house at ground level, rooftop, and on a 12 meter tower. Main concern was the EMI emissions from TV's, PC's flourescent lights etc. in a suburban high density housing tract.

For EMI, it was worse at ground level (2-5 meters from the house). Less EMI on the rooftop (5 meters above ground) and least EMI on the tower. That was LF through 30 MHz.

As far as signal strength of LF beacons and local MW broadcasters, the signal strength was best at ground level measured at about 2-6 dB higher than at the tower elevation.....however, the EMI was also much higher. For SW above about 4-8 MHz, signal strength of ham and broadcasters was higher on the rooftop as well as even higher on the tower.

Hope this helps

Alex

With a friend I am in the process of building a magnetic unturned active loop of about 1 meter diameter for each of us for general and ham band listening.
I have often seen remarks that these loops perform best at a few meters above ground level.
Has anyone got any experience with the use of this type of antenna on a rooftop.
We have the option of placing this antenna on the flat concrete roof of a flat building of about 30 meters height, any advice?
How would this compare with the positioning of this same antenna on the balcony railing somewhat lower?

I hope someone can fill in the voids in my own experience.

I have designed PCB to build my own L Z1AQ amplifier at home. I want to share CAD project with comunity - to open it you need to download and install DipTrace program (http://www.diptrace.com/?en=1).

Best regards,
Pavel

it might work even better if you replace R8 with a ground gate JFET like J310 or J309 otherwise looks pretty good, I note R4 and R5 has double duty as part of base bias and negative feedback best Paul _____ From: "everettsharp@..." DL2KQ says you MUST elevate the loop, especially if it is relatively large: http://dl2kq.de/ant/3-73.htm
Please try to use Google Translator or any other. This is extremely interesting article, written by DL2KQ.
For those who doesn't know: this guy published 6-part Antenna theory book, as well as re-build first the known MMANA modeling SW, then made a new one, GAL-ANA, which is very popular today among antenna manufacturers.
I think that with only limitation -written in Russian- this web site is most comprehensive antenna-related web site today.

---In loopantennas@yahoogroups.com, <loopantennas@yahoogroups.com> wrote:

It's not necessary to elevate a magnetic receive loop as the pattern is the same whether at ground level or 30 feet above ground. If you do elevate the receive loop the vertical or near vertical run of coax feedline will pick up noise in the local field which will defeat the S/N improvement that one normally looks for in this type of antenna.

This problem can be pretty much solved by adding coaxial choke BALUNS at the feed point of the receive loop and at the radio shack service entrance. But it's not a fool proof solution.

Check out my receive loop web page at http://www.wcflunatall.com/w4hm14.htm

Hello Everett, Three years ago the M0AYF antenna was also discussed in this group, Chris Trask gave the following contribution to the discussion (2010, July 20): “One item I find missing from this design is an input BalBal transformer. Such a transformer would serve a number of uses, in particular providing a degree of immunity from common-mode interference such as lightning strikes. It would also provide a ground reference for the antenna proper, and in addition would allow the two transistors to have an identical base voltage. The limiting diodes would be placed across the primary side of the transformer. I would also disconnect the two emitters, have a separate biasing resistor from each emitter to ground, and then a suitable capacitor between the two emitters. Then the two capacitors from the collectors to the output transformer primary winding can be eliminated. The 1:1 UnUn output transformer could be replaced with a 1:1:1 BalUn, the centre tap of the primary connected to the supply line. This would increase the P1dB a bit plus raise the gain by an additional 6dB.” I built the original circuit, but I’m planning a further one along Chris’ recommendations. In your document about your experiments with Moebius loops you were not very positive about the M0AYF design. Hello Göran,

Does it means that you advise to put the antenna high on the roof instead of somewhat lower on the balcony?

We will certainly compare the two situations after completion of our loops.

The amplifier we will use is not decided yet, I'm going through all the designs I have been able to find up to now. I do not have an education in electronics so I have to rely on what others mention about the subject.

Thanks for your reaction.

Cor Beijersbergen

Hello Thomas,

We will certainly do some experimentations with common mode filters on the coax.

The Web page you mention about your receiving loop was already in my collection of articles on the subject, I will read it again.

Tnx,

Cor Beijersbergen

This problem can be pretty much solved by adding coaxial choke BALUNS at the

feed point of the receive loop and at the radio shack service entrance. But it's not a fool proof solution.

Check out my receive loop web page at http://www.wcflunatall.com/w4hm14.htm
.

Hi Cor, I have not seen any of Chris's writings below, however, Steve Ratzlaff, is the one that filled me in on changing the coils to connect directly to the Collectors on Q1 and Q2, I found out through experimenting that the amp worked better using 1 uF cap, rather then the .01 uF that it called for between the amp and the loop. Yesterday I made another change to the amp by removing the two 100 ohm resisters feeding the two coils and changed transistors. Now it works even better yet. It is now drawing 55 ma @ 8.25 V, whereas it was only drawing about 35 ma at the same voltage. I also changed the transistors to MPSH-10, thus replacing the 2N2222's. (Note: if you are considering using the MPSH-10 transistors, the pin outs are different than the 2N2222, rather than E, B, C, they are B, E, C, I found out the hard way) I tried it on the Mobius and it worked okay, but I was not able to get the 30 dB nulls, so I tried a 1:1, 1:2 and a 1:3 matching transformer and with the 1:3 I was able to get the 30 dB nulls. Also I noticed that it worked much better up band on 10 meters. Today I will compare it to the Clifton Z10046A amplifier. I am happy with the mobius loop, using the PEX AL PEX pipe, as I am able to get deeper nulls with it than a conventional shielded loop. Also it is way better than a 1 meter wire loop, as it has a lot less noise and you are able to null out most noise with the mobius. For the mobius to work well you need to get the capacitance down and you just can not do it with off the shelf coax. If you don't have, or can't get the PEX AL PEX pipe, then you could make up a coax loop like I did in the article. However, you need to have the loop capacitance down to 150 pF, or below, if you want the 30 dB nulls. It still works well above that, but you will not get the 30 dB nulls. I was only able to get 25 dB nulls with the home made coax loop, but other than that it worked as well as the PEX AL PEX mobius. Everett In a message dated 10/7/2013 2:41:01 A.M. Central Daylight Time, dx11@xs4all.nl writes: Hello Everett, Three years ago the M0AYF antenna was also discussed in this group, Chris Trask gave the following contribution to the discussion (2010, July 20): “One item I find missing from this design is an input BalBal transformer. Such a transformer would serve a number of uses, in particular providing a degree of immunity from common-mode interference such as lightning strikes. It would also provide a ground reference for the antenna proper, and in addition would allow the two transistors to have an identical base voltage. The limiting diodes would be placed across the primary side of the transformer. I would also disconnect the two emitters, have a separate biasing resistor from each emitter to ground, and then a suitable capacitor between the two emitters. Then the two capacitors from the collectors to the output transformer primary winding can be eliminated. The 1:1 UnUn output transformer could be replaced with a 1:1:1 BalUn, the centre tap of the primary connected to the supply line. This would increase the P1dB a bit plus raise the gain by an additional 6dB.” I built the original circuit, but I’m planning a further one along Chris’ recommendations. I built and modified the M0AYF amp for better Imd performance, and used it for some time. I've also built 2 of Chris's, 2 Nortons, the LZ1AQ and some (mediocre) attempts of my own. The stock LZ1AQ design built ugly style, with a single fat 80cm diameter copper loop has for me, been the most consistent performer for general HF listening. I think much depends on requirements and operating conditions. My main problem is strong local noise, something the M0AFY didn't handle well even when modified, or with a shielded loop.

I hope this gets to the list, for me using the web interface Yahoo groups are broken, almost impossible to follow post threads.

Based on both, actually. I use it as standard design practice to avoid common-mode distortion at every stage whenever practical.

Hi Steinar,
When I tried to read about the Hidroil capacitor I could never download the full page. For some reason my browser would lock up when trying to download the full page. Sorry to say I cannot read the language either.

Could you describe to us what the Hidroil capacitor is? It looks like someone put together an interesting high-power capacitor for a transmitting loop antenna with some kind of built-in motorized tuning and remote control? It looks like nice wide copper tabs to make connections to the loop.

Is the capacitor immersed in some kind of oil? What does the 30/700 number stand for? Thanks for any additional info.

I did a little searching and found this page. Looks like you were spot on!

http://r.twenga.es/g3.php?pg=VDs1OTkzNjU3Nzk4MTg2MjI2NTk2OzU4MDI1MTc7aHR0cDovL2luYWMtcmFkaW8uY29tL0NvbXBvbmVudGVzL0NvbmRlbnNhZG9yZXMtdmFyaWFibGVzLWRlLWFpcmUvQ29uZGVuc2Fkb3ItdmFyaWFibGUtZGUtMjAzMzBwRi1IaWRyb2lsOzZjYmY1Mzk0ZmZmMzhhNWE0N2E1Yjk4ZDZiMDZhYzk2&dac=4 http://r.twenga.es/g3.php?pg=VDs1OTkzNjU3Nzk4MTg2MjI2NTk2OzU4MDI1MTc7aHR0cDovL2luYWMtcmFkaW8uY29tL0NvbXBvbmVudGVzL0NvbmRlbnNhZG9yZXMtdmFyaWFibGVzLWRlLWFpcmUvQ29uZGVuc2Fkb3ItdmFyaWFibGUtZGUtMjAzMzBwRi1IaWRyb2lsOzZjYmY1Mzk0ZmZmMzhhNWE0N2E1Yjk4ZDZiMDZhYzk2&dac=4

For those who can't even see the above link..

http://tinyurl.com/hidroil-cap

It seems to be another page from the same vendor but with a different illustration.

Here is the description...

"Variable capacitor, with servomotor. 20/330pF 7.5 Kvols.
In airtight ABS. Condenser motor and immersed in a dielectric HIDROIL.
With tubing connection 28mm bronze. You can request other connection.
Condenser for conducting a large loop antenna performance."

7.5 kV! I guess that is for a rather high power transmitter.

Rick

A pot geared into the capacitor drive fed into an ADC would give a good indication of the position of the capacitor.

I am building (slowly!) a remote tuned receive loop. It uses a garden variety superhet variable capacitor and since I only needed 2 of the 3 banks of the capacitor (and the 3rd had less vanes) I removed all but one of the vanes in the 3rd bank and cut the remaining middle vane to use it as an interruptor which triggers opto endstops.

In the original software version, I would step the capacitor to one endstop, then count the number of pulses needed to get to the other endstop, and then I knew exactly where the capacitor was by keeping track of pulses fed to the stepper.

In the current version, I don't even bother doing that. When the unit is turned on, where ever the capacitor is at the time is position 0, and I keep track of the pulse from there, giving positions that can be -ve of +ve. The arduino knows what frequency the radio is tuned to, and I manually tune the loop with push buttons, and when peaked I store the capacitor position in memory and the arduino then knows what capacitor position to move to when the tuner is at frequency x. Once I've stored a few positions across the band, the arduino can estimate the correct capacitor position, and as I manually peak each position, the arduino stores more data points and can more accurately esitmate. The arduino has an LED to let me know when it's on a frequency that has been manually peaked. After a few minutes of tuning around the band, the loop is fully tuned, and I can then just move the receiver frequency around and the loop auto-tracks it.

You have to be careful you feed the pulses to the stepper at a pulse rate the motor likes, or some pulses will be lost and your positioning data goes pear-shaped.

Once I repair my R8 (it has corroded internal "TMP" rf connectors - and I'm having trouble getting replacements), I'll put a video up.

A pot geared into the capacitor drive fed into an ADC would give a good indication of the position of the capacitor.

I am building (slowly!) a remote tuned receive loop. It uses a garden variety superhet variable capacitor and since I only needed 2 of the 3 banks of the capacitor (and the 3rd had less vanes) I removed all but one of the vanes in the 3rd bank and cut the remaining middle vane to use it as an interruptor which triggers opto endstops.

In the original software version, I would step the capacitor to one endstop, then count the number of pulses needed to get to the other endstop, and then I knew exactly where the capacitor was by keeping track of pulses fed to the stepper.

In the current version, I don't even bother doing that. When the unit is turned on, where ever the capacitor is at the time is position 0, and I keep track of the pulse from there, giving positions that can be -ve of +ve. The arduino knows what frequency the radio is tuned to, and I manually tune the loop with push buttons, and when peaked I store the capacitor position in memory and the arduino then knows what capacitor position to move to when the tuner is at frequency x. Once I've stored a few positions across the band, the arduino can estimate the correct capacitor position, and as I manually peak each position, the arduino stores more data points and can more accurately esitmate. The arduino has an LED to let me know when it's on a frequency that has been manually peaked. After a few minutes of tuning around the band, the loop is fully tuned, and I can then just move the receiver frequency around and the loop auto-tracks it.

You have to be careful you feed the pulses to the stepper at a pulse rate the motor likes, or some pulses will be lost and your positioning data goes pear-shaped.

Once I repair my R8 (it has corroded internal "TMP" rf connectors - and I'm having trouble getting replacements), I'll put a video up.

Hi Todd,

I am sorry for not responding earlier. I have had a lot of work to do lately.

Yes , I think it is a motorized tuning and remote control for a capacitor .

I can not read the language, but I am using Google translator.

I was doing a Google search and came across this page (translated from French to English):

http://translate.google.no/translate?hl=no&sl=fr&tl=en&u=http%3A%2F%2Fj28ro.blogspot.no%2F2013%2F05%2Finac-ah-521-antenne-loop-magnetique.html

The antenna is us using the capacitor, and the system seems interesting.

From: Ron Polityka
Topic: 10225 Message: 10225

Hello,

Just wondering if there would be a use for the old military tuners that I have in the shack.

Look down at the bottom of the page for the pictures.

http://www.wb3aal.com/4-Sale.htm

If any one would be interested, make an offer. The could be going to the scrap yard next week.

73
Ron de WB3AAL

FYI - I am on the Digest mode for the list. If interested, please e-mail me direct.

Ron: Suggest you join the Milsurplus qth.net reflector and list the tuning units there. Go to https://qsl.net/ , go to email mailing lists, then Directory of Lists, search for Milsurplus, and click on it.

Has anyone experimented with phasing a rotatable loop against an active whip or vertical? I have a Pixel Loop and a DX Engineering vertical and I have just begin playing around with phasing them through a DXE NCC-1 phaser. I often like then end results but it's a lot to adjust

a) loop direction
b) loop gain
c) vertical gain
d) phase
e) relative balance between the 2

Any tips or suggestions would be greatly appreciated.

Ian, I used to do something similar to what you have described many years ago. I soon came to the conclusion that the whole excise is a waste of time. The main reasons are; the achievable null is too narrow in relation to frequency. The nulls are not stable with time i.e. small variations is signal arrival angles. The later makes the system unusable for HF. The DXE phaser is not suitable for wideband operation i.e. it can't provide a constant phase shift with varying frequency. This would be a essential requirement when phasing a loop with a whip because a constant 90 degree phasing +/- any antenna phase variation is required.

Maybe someone else in the group could recommend a 2 input SDR that could provide constant phasing verses frequency????

A small improvement can be had by using a longwire antenna for the Vertical instead of an active Whip.

If your interest is mainly phasing for LW and MW and you want the phasing to the be stable over a wide bandwidth, then you need to use identical antennas and a variable crossfire phasing unit. For example the type used on some of Wellbrook's Phased arrays.

A compact 360 degree system could be a Wellbrook Phaser and 4 Clifton Labs Active Whips, these offer much better IMD performance compared to Dxe whips. Or you could use 4 ALA100s. The recommended minimum antenna spacing is 20m

However, if you just need a wideband rotateable antenna with a cardioid pattern, then consider a small Flag antenna. This can be home made or one could use commercial Head Amplifier.

I have had outstanding results using a Dallas Lankford-designed phaser on medium wave using a rotatable M0AYF loop and a Steve Ratzlaff active whip both located in my back yard about 30 ft apart. Steve kindly loaned me one of his Lankford phasers to try and it is the best one I have ever used.

You can read about the Lankford MW #2 Phaser at this address :

http://docs7.chomikuj.pl/1992228534,PL,0,0,MW-Phaser-%232.pdf (http://docs7.chomikuj.pl/1992228534,PL,0,0,MW-Phaser-#2.pdf)

The phaser in the article is optimized for medium wave but it can be easily modified for SW use also. The one I am using has six bands from the 300 kHz to 14 mHz range.

The Lankford phaser is more forgiving than most on signal levels from each antenna and they don't have to be perfectly matched although you can get the best nulls if signal levels from each antenna are roughly equal. For best results with the phaser the loop should be rotated for best signal from the offending station, not a null.

With the Lankford phaser I am able to null out a local station on 1490 kHz 12 miles away right down into the noise level and hear another distant station on 1490 almost exactly 180 degrees opposite, something I was never able to do with a loop antenna alone due to the figure 8 pattern of the loop.

Once I set the Lankford phaser it remains stable for days on end.

I also have a Quantum Phaser and I would rate it a very close second. The Quantum has only 3 controls to adjust and the settings are a little more critical, but once adjusted I would say the nulls are about equal to the more complicated Lankford phaser. If someone did not want to have to build their own phaser I would recommend the Quantum phaser.

Using a broadband loop and an active whip are one of the best combinations for a phaser and requires the least spacing between the two antennas.

I designed my own a few years ago, and I added the brief PDF file "Antenna Canceller Prototype 02.pdf" to the group files section. It is used with an orthogonal pair of loops for both noise cancelling and electronic steering, and can also be used with a loop and whip combination.

10232. Rolled a loop using a Harbor freight tube roller

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-10-20 15:00:10 UTC
From: everettsharp@...
Topic: 10232 Message: 10232

Hi Guys.

I just finished rolling a 10' long piece of 3/4" hard, type L, copper tubing that I picked up this morning at Home Depot, using a Harbor Freight Tube Roller. The outside diameter of the copper pipe was 7/8". The smallest roller diameter that comes with the HF tubing roller is 1", which worked out okay. It took about 10, or so, passes (less than 5 minutes) to finish the loop. I only took half turn adjustments with the adjustment screw on the drive roller, with each pass.

The other rollers that come with the Harbor Freight tubing roller are 1.5" and 2". There is a after market seller of other size rollers and I may invest in them later. The main drive roller does have ball bearings that the shaft runs through. I know that HF sells a lot of junk, but this tubing roller is a good value.

If anyone is interested in buying one you can look on line at the HF site, you will have to type "tubing roller" into the search to find it. The sale price is $169.99. If you do a online search for HF coupons you should be able to fine one for 25% off, thus making the cost around $127 + shipping. They also have a $6.95 FEDX shipping deal too.

The finished loop look very nice and it ended up at about 1 meter in diameter. In the next few days I plan on rolling some 1.5" 6061 T6 Aircraft tubing, which is 12' long.

Thanks for all the replies.

I would love to set up some type of 4 square phased array but I think I am pushing it now with my HOA. The last place we lived the HOA made me take down all my antennas and I don't want to risk what I already have.

Interesting comments re the DEX phase. I have Quantum phaser packed away, haven't used it since I upgraded to the DXE unit. I think I'll pull it out today and see how it does.

Andy's comments re the fussiness of the nulls using this set-up is spot on . It's why I give up using it every few days and then pack the phaser away for months. It wasn't a good investment of $600...

Thanks again.

The schematic shows one winding of T4 shorted!

Is this an error in the schematic? If not, one could eliminate T4 and just use a solid wire connection.

Thoughts?

Yes, it's an error on the schematic. Transformers T4 and T5 should be connected just as T2 and T3.

Re : The Dallas Lankford MW Phaser #2 Schematic

No the wiring for the secondary of transformer T4 is NOT in error. Yes both sides
of the winding are connected to ground but this is part of the phasing circuit.
Remember the toroid winding is at RF potential so the windings are not actually "shorted" for RF.

For example look at a one turn transmitting loop antenna. It looks like a direct heavy short but NOT at RF.

I am holding the Lankford phaser in my hands right now and both sides of the
T4 secondary are connected to ground. Chris Trask is in error about this circuit.

In a message dated 10/20/2013 12:20:05 P.M. Eastern Daylight Time, jbollit@... writes:

The schematic shows one winding of T4 shorted!

Is this an error in the schematic? If not, one could eliminate T4 and just use a solid wire connection.

Thoughts?

Then we should consider that the purpose of the shorted T3 is to compensate for the parasitics of T1. Then it makes sense.

For those who have built this, what are the results of replacing T3 with a piece of wire?

Chris

Chris,

I have built one.

When you say "replace with a wire" are you talking about a single turn through the core, or leave the other winding on T4 (at the only winding on the core) and repalce the shorted turns with a piece of wire that does NOT pass through the torroid?

Or is there something else you want me to try.

I have my phaser open, here on my bench.

Let me know.

Jim

Remove T3 entirely and replace the broken primary winding connection with a piece of wire.

Todd WD4NGG: The Lankford phaser is more forgiving than most on signal levels from each antenna
and they don't have to be perfectly matched although you can get the best nulls
if signal levels from each antenna are roughly equal. For best results with the phaser
the loop should be rotated for best signal from the offending station, not a null.

Todd,

So what you're saying in my case if I am looking to null all the Cuban pests S/SE of me I should point the loop S/SE and phase that against the whip rather than pointing the loop 90 degrees which weaken the Cubans considerably and phasing from there.

Thanks very much.

Chris,

I will do this.

Need to connect phaser to antennas per schematic and get a base line on a station.

Then will do the shorted wire test.

Will advise.

Hi Ian,
Yes when using a loop with a phaser the loop should be pointed at the offending
station or stations for maximum signal pickup, not broadside or oriented for
a null. You want Max pickup of the offending station or stations with the loop.

It sounds counter-intuitive at first to point the loop for max pickup of the station
you want to null but that is what works best with the phaser.

>
> 73,
> Ian
> Florida,US
>I had done a lot of research online and asked a lot of questions here and on the chat for MWDX ,eventually i settled on this , I have been using this setup for 2 years :

Pixel Pro1A Loop
Cheap rotator from E.bay (for use on the loop on top of a 10 foot section of Rohn tower).
MFJ Remote active antenna (12-13 feet (East) of the loop,and grounded with a 8 foot copper pipe).
Quantum Phaser .

The whole thing is 50 feet from the house fed with RG6 coax ,buried in a slit trench.

At first i had trouble with what i was doing then all of a sudden one night i could chose which station i wanted to hear ,and they were 180 degrees from each other ,turns out that this setup can not handle sky-wave signals well,on those nights i just don't use the vertical or Phaser. Sky-Wave signals come from high angles so it's hard to use the null in any effective way .

Has it Brought me DX ? YES!!!
Was it worth it IMHO ? Yes!!

You need to now that my listening position is nearly in the center of North America ,so i need to be able to have some kind of steerable antenna to get the tuff ones .I have pulled Flea power station out from under 50KW flame throwers if the conditions are good ,if they are bad i don't get much.

I live 3 blocks from a 1KW station on 1350 ,there is no point DX ing until they power down at night and even then i have trouble around that Freq .

My log book includes both the west and East coast (I only DX at night),anyway you being in Florida about the only advantage i see would be Trans ocean DX as most of your signals will be coming from the W-NW direction?

The most important thing i did was grounding the vertical,after that was done ,the noise floor went down on that antenna ,and when lightning strikes are near they are less noticeable.

Normally i run the -20DB attenuator in the on position on the vertical ,it just seems to operate better with the pixel that way.

The pixel loop is normally very quiet ,however there are some times when conditions are not favorable for it.
It seems to me there is no perfect setup as far as antennas go ,but this one is pretty close?

I've been told that you can have zero separation between the vertical and loop but this is where i had a structure to place my setup so i have never tried it that close? it would be interesting to try it some time.

Yes it can be rather daunting to try and adjust this but after a while it becomes pretty easy ,some times no matter what you do you just can not get a clean copy ,when that happens i just move on and come back to that freq for the next 2 nights ,you would be surprised how many times I get that ID .

Any other questions ? let me know :)

I read this on JD's Loop Home page:
http://www.frontiernet.net/~jadale/Loop.htm

(4) Also please note that a balanced loop antenna can be spoiled to a cardioid pattern by putting a vertical sense antenna within its field.

Would some be so kind to explain to me how this would be effected? It sounds like a great idea in theory if the f/b ratio were any good. Where precisely would I place a whip to effect this?

Thanks very much.

Hello guys,
I would like connect my ALA1530 with my REMOTE COAX switch by Ameritron mod RCS-8VX.
Probably I have to connect the amplifier (and relative power supply) between Antenna and one of the 5 output of remote coax switch. Please confirm me...

Anybody have a situation like me ? Any suggestion for a better configuration?
Also , please note that remote unit of coax switch is driven by STATION MASTER from microham.

Thanks for any help and

Magnetic Loop antenna's tuning caps require the plates to be joined together (welded) no contact or wipers I did not see that you were doing this. I would love buy some of these variable caps but need the plates welded together. Do you do this or have someone to do this ?

Is this really necessary in a butterfly capacitor? Doesn't the current flow from one set of vanes on one side to the other?

On a regular non-butterfly air variable capacitor the current from the individual vanes will 'sum' at the rotor and pass through the wiper ... but in a butterfly design doesn't the current traverse from say, the left vane to the right vane? If the vanes are one-piece, what would be the value of welding or soldering them to the rotor?

Jim

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1. * Justice AM Loop Antenna (Active)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Long LoopStick Antenna for MW DXing
Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

10256. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-11-01 11:49:48 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 10256

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

10257. Sheilded loop design

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-11-02 05:24:33 UTC
From: colin
Topic: 10257 Message: 10257

Hi,

I am new to this group and looking for a design for a shielded loop.

regards

10259. FSL antenna for sale

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-11-02 14:13:30 UTC
From: <everettsharp@...>
Topic: 10259 Message: 10259

If anyone is interested I have for sale a "One Of A Kind", 12" Diameter by 7.5" wide Tri-Coil Dual Band FSL. It covers both LW and MW bands, in two bands, MW 1745-470 KHz and LW 630- 150 KHz. It works very well and is a work of art. It can be used in an induction coupled, or 50 ohm configuration to your radio. The price is $500+, an estimated shipping cost, of $35 to $40. I will take PayPal payment. You can contact me off list at everettsharp (at) AOL if interested and I can email you more information and pictures. I wrote an article on this FSL and it is posted in the files section of several of the Yahoo sites.

I have too many antennas and it is time to downsize.

Everett N8CNP

10260. SSTML Antenna

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-11-02 22:56:41 UTC
From: Mike N9LSD
Topic: 10260 Message: 10260

If this post is OT, please tell me. I have a kenwood R-2000. Im also very weary of using it with a random longwire antenna.. I found the single turn receive-only antenna (subject) design . Does anyone have SWL experience with this antenna? I want to use it to hear Russian and Euro. Folk music. I live in Indiana. Feedback and comments very welcome. Mike N9LSD

10261. Commradio CR-1 For Sale

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-11-03 13:34:06 UTC
From: <everettsharp@...>
Topic: 10261 Message: 10261

I have for sale a Commradio CR-1, with battery, SN# 25, it is in like new condition. It has had both the encoder and main circuit board replaced (Rev. E). It is in perfect working order and has all the updated frameware installed. Also included with it is a, home made, broadband loop amplifier, that works off a 9 volt battery. You can hang a wire loop in your window and hook it to the amp and it works as well as most outside antennas..

The CR-1 has way better DSP then the Icom R75 and is outstanding on SSB. You can get all of the specifications on the Commradio web site http://commradio.com/ http://commradio.com/

I just have too many radios and it is time to downsize.

I am asking $500 for the CR-1 and I will pay the shipping to anywhere is the US. Commradio's current price is $599+shipping. Their lead times for the CR-1 are 3 to 4 weeks.

If anyone is interested please contact me off list at everettsharp (at) AOL

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

2.1. File - UploadingFilesLinksPhotos.txt
    Posted by: loopantennas@yahoogroups.com
    Date: Fri Nov 1, 2013 4:49 am ((PDT))

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

10263. 1.5-volt active loop antenna?

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-11-05 03:32:58 UTC
From: <qrp.gaijin@...>
Topic: 10263 Message: 10263

Greetings list members,

I have built the M0AYF active broadband loop antenna described at the link below. It works well (I use 2N3904 transistors).

http://www.qsl.net/m0ayf/active-loop-receiving-antenna.html

I am wondering if it is possible to run this antenna off of very low voltage, 1.5 to 3 volts. What would be the recommended changes to the circuit, and what would be the likely impact on performance?

The reason for wanting to run it off of low voltage is that I want to incorporate this antenna as part of a low-voltage homebrew transistor shortwave receiver. The receiver itself runs off of 2 AAA rechargeable batteries. It would be nice if I could run the antenna off of the same power source.

Any comments appreciated.

10264. saturn 6m halo loop

You could, but the IMD (distortion) performance would be severfely impacted. You could approach that problem to some degree by replacing transformer T1 with high turns ratio, perhaps 1:9, so that the transistor collectors will see a very low load impedance. This will greatly reduce the signal voltage so that there will be a lesser tendency for the transistors to approach saturation or cutoff.

Also, the biasing arrangement will need some serious modification. I have a schematic in mind if you're interested.

Chris

Thanks for the suggestions. Yes, I would be interested in any further schematic details you might provide, even if only tentative.

As an experiment I tried running the antenna off of about 2.4 volts, with no circuit changes. The loop element is about 2.5 meters of copper foil shaped into a diamond. Though signal levels were lower than normal, the antenna did work reasonably well indoors for SWBC listening, and I could hear a few hams on 40m as well. I noticed no IMD, probably because the concrete building kept signal levels low enough to avoid problems.

Chuck,
I'm not sure what a saturn loop is.

But in 1962, I was in Elimra, NY and at the club we made horizontal loops for everyone. there were three loops stacked on top of each other and was approx 2 feet in Dia, we used it mobil and for fixed station...

really worked well. wish I had it today, but someone thought they should have it and it went missing.

I don't know if anyone else has a plan etc for that mobil hallo or not.
I'd be interested if someone does have plans.
I haven't seen any, but still looking.

I hope you enjoy your 6M loop as much as I did.

Blessings and 73's

Attachments: 1 described; binary payloads are missing from this source WARC

Even if you could, the current drain between the amp and the receiver would kill 2 AAA batteries real fast. The gain of the amp would be reduced to almost nothing with 1.5 volts anyway.
I use the same amp almost everyday, but I supply it with 13.5 volts via the feedline .

Thank you Chris.

Your mobius strip shielded loop design is very extensive!

I have aquired a 32' run of 1" diameter semi-rigid 50 ohm coaxial cable.
Do you think it would be suitable shielded design?
I am aware that having a relatively large inherent capacitance will limit it's upper frequency limit.

Regards
Colin

I just added the file "Active Loop Amplifier for 1p5V Operation.pdf" to the group files section. I should point out that for loop antennas the input impedance of the amplifier should be very low, so I will later add a schematic for a more suitable design later.

Good IMD performance at low voltages will be tricky. You'll notice in the schematic that the biasing is accomplished by way of current mirrors so as to maximise the emitter-collector voltage.

You don't want to run low-voltage amplifiers at high currents as the saturation voltage rises with current, and you soon find yourself with a limited dynamic range. Take a look at the curve family photos in my paper on transistor selection at:

http://www.home.earthlink.net/~christrask/Bipolar%20Transistor%20Evaluation.pdf

That would be terrific material for making a MW to 49m shielded loop.

Fond memories of the Saturn 6 here. It was the "go to" 6 meter mobile antenna in the midwest back around 1961 when I was first licensed. Proudly had one on the back bumper of my 1950 Chevy coupe. Rig was a Heathkit Sixer.

As I recall, it was basically an end loaded dipole with appropriate matching. Once you had the little tuning plate between the ends adjusted just right, it worked quite well.

Thanks for the ideas. A couple of questions, if I may:

1. The emitter resistance has been replaced with an inductance. Will its reactance variation with frequency affect the wideband nature of the loop? A similar question apples to T1, which seems to replace the original base bias resistors going to ground (R6 and R7 in the original M0AYF schematic).

2. How should the values for R1, T1, L1 be computed?

It will be interesting to build the new circuit and see how it compares to the original amplifier circuit (run off of both high voltage and low voltage). As I mentioned, with the original circuit, 2.4V was, somewhat surprisingly, enough to deliver audible reception of ham and SWBC signals with the antenna indoors; 1.2V operation was, however, impossible and yielded no audible stations.

> I should point out that for loop antennas the input impedance of the amplifier should be very low, so I will later add a schematic for a more suitable design later.

I look forward to seeing this design when it is ready. Differential pairs are still a bit of a mystery for me, but I'm learning that they have a lot of uses in low-voltage applications: as oscillators, regenerative detectors, or, as we see here, loop antenna amplifiers.

The purpose of the inductance is to retain the differential nature of the amplifier. At low
frequencies, the amplifier will become a pair of common-emitter amplifiers. The
differential amplifier provides immunity from common-môde distortion.

>

Transformer T1 acts as a biasing choke, and it provides immunity from common-môde
interference, such as from strong nearby broadcast signals.

>
> 2. How should the values for R1, T1, L1 be computed?

The values for T1 and L1 will depend on the lowest frequency of interest. The value for R1
is chosen so as to provide the best IMD performance.

Let me work on that. I finished off the schematic for the low input impedance amplifier, so I'll incorporate that as well. It will use the HFA3046 NPN transistor array, which is a good device for low-voltage RF applications such as this.

I just deleted that earlier PDF file and replaced it with "Active Antenna Amplifiers for Low Voltage Operation.pdf" that has the low input impedance amplifier on the second page. This is still a work in progress.

Not certain what sort of gain to expect with either of these. The maximum supply voltage will depend on the collector-emitter breakdown voltage of the devices. For the low impedance amplifier using the HFA3046, the maximum supply voltage would be 5.0V.

Hi Bob,

There is an article in the November issue of ARRL's QST magazine about the Walkham version of the Alex Loop. The reviewer gave it pretty good marks. Said it's available from GigaParts and another vendor (I can't remember the name).

The GigaParts page is here ...

http://www.gigaparts.com/Product-Lines/HF-Portable-Antennas/PH1AHD-AlexLoop-Walkham.html

At $369.00, it's pretty pricey, IMHO.

73,

Steve N5WBI

Yes,pricey.Also,very well constructed,easily portable in it's carrying case,and very effective.I have worked lots of dx with it,including DXpeditions on Swains Is,Niue Is,and into Tasmania on 10w.Pricey yet a nice product for portable qrp ops.Other antennas are also pricey,but they do not work well.This one does...Dennis W7KB.

Hi Bob,

There is an article in the November issue of ARRL's QST magazine about the Walkham version of the Alex Loop. The reviewer gave it pretty good marks. Said it's available from GigaParts and another vendor (I can't remember the name).

The GigaParts page is here ...

http://www.gigaparts.com/Product-Lines/HF-Portable-Antennas/PH1AHD-AlexLoop-Walkham.html

At $369.00, it's pretty pricey, IMHO.

Hi Guys,

Too bad that Gigaparts mistyped and uses now a Dutch (prefix) callsign as typenumber.This could give quite some confusion in the future.

This is a 1-minute audio segment http://moondogastronomy.blogspot.com/2013/11/4703125-mhz.html, taken from a Uniden Bearcat hand-held scanner tuned to 470.3125 Mhz. It is part of a 2.5 hour period from 0800-1030 UTC on Nov. 9, 2013.
Included is my SpectrumLab plot as well as the Planetary K index for Nov. 9, 2013.
Can anyone tell me if this audio is a result of the aurora activity at that time? If not, what could I be picking up at that frequency? Thanks.

Jim Tegerdine

Hi Jim, it could well be due to the aurora as while Ive been laid up in the house due to medical problems I have been listening around on the FSR 446mhz band where my own low powered personal radio link is located and heard some amazing lifts with only a small indooor 1/4 wave ground plane antenna, I live in the heart of northern england in a place called Hexham in Northumberland down in a steep river valley with tree lined steep hillsides either side and to the rear of me and I have still heard mainland europe stations using 1/4 watt hand portable devices on 446 quite clearly and the build up (lift) sounded very similar to what you have, when you notice it again get down to the 70cm ham band or the 446 fsr segment and see what you can hear you may be supprised.

Phil....
Thanks for the confirmation. Right now, (1330 utc) there seems to be some slight build up. I noticed on spaceweather.com that there is a 40% chance of aurora activity due to a solar wind sweep today (11/10).
I'll check the other frequencies.

Jim

It has got so bad lately that myself and a few others who run radio gateways on 446 linked to the internet have had to either switch to tone squelch opperation (like I have done) or have the squelch on the gateway radio set up to nearly max to stop them switching to tx due to the static lift, I reviewed your recording and it does not sound like any of the usual man made interferance we hear on the bands from flouresant lights, pump motors, generators, PLTs or thermostats so more than likely solar or aurora.
Do you live near any military or naval bases that do testing or radar? it could also be that as the MOD are sometimes active around those frequencies.
Hope you pin it down

Phil

I live close to the Jim Creek Naval VLF station. But I don't think that would cause any interference.
I also monitor VLF for SID (Sudden Ionospheric Disturbance) and Jim Creek (NLK) generates a very strong ground wave on my receiver. I am about 12 miles SW of the station!

You are probably going to need more than where to connect as there are three variable capacitors on that honker. There are solder terminals on the top of that that image over each bank;again, for your application you will need to know which banks to hook up.

That thing is waaay bigger than the 2 i have. Fyi- for any app. Over 800W. Youll need to use at least 16 ga. solid wire.

Three? I count five.

You could parallel all of 'em. Or switch them in and out as needed.

It depends on what you want to use the capacitor for.

The pictured capacitor has two sections used for tuning
the AM bcst band, probably 365 pF each, the sections
with many plates. There are three sections of capacitor
used for the FM band,more likely in the range of 30 pF each.
There is a tab above each capacitor section. The other side
of all the capacitor sections is the capacitor frame. The four
screws on the top of the cap are find adjustments for that section.

For use tuning a loop, this is only suitable for receiving antennas.
Moderate or high transmit power would create high voltage
across the capacitor plates and arc over.

For use as an HF or bcst band receiving loop, one of the lare
sections would be used, or possibly, both large sections in
parallel.

I am making an alex loop mag antenna. I have lots of 12 ga romex with I can split for the copper wire.

If I connect the 3 banks together of on each side and then connect them each to an so239 will that give me proper connections ?

isnt the voltage capacity mostly dependent on plate spacing? For 2.5 KV I think youd need roughly .06" my 2 out of a Viking II are only .03" and that was a standard transmitter.

Hi Jim,

I did find you a number of pages so you can study them at your own pace.
When you want to discuss these or anything else feel free to contact me off groupso we can go into detail.
1) http://en.wikipedia.org/wiki/Space_weather2) http://spaceweather.com/3) http://en.wikipedia.org/wiki/Tropospheric_scatter4) http://en.wikipedia.org/wiki/Troposphere5) http://www.dxinfocentre.com/tropo.html
The last page is very easy to use.It will predict, with very high accuracy, conditions.
I hope this info helps.
Best regards,
Rob PE9PE

jtegerdine@yahoo.com , 11-11-2013 1:38:

Rob--

Can you steer me to more info on tropo?

These signal lifts seem to coincide with solar wind density, but I'm fascinated in learning more...

Jim

---In loopantennas@yahoogroups.com, <rob@...> wrote:

Hi Jim and Phil,

I'm sorry to both disappoint you, but this has nothing to do with Aurora.
You are both confusing TROPO with Aurora.It's an often made mistake, but so what, we are here to learn isn't it?
Aurora has been only once or twice been recognised as lifting conditions on low UHF.It usually, say 99.9999% never reaches 200 Mhz or higher, let's even so high up on the 400MHz band.
Jim what you have recorded, imho, is a slow fading signal/carrier via tropo. I t can be anything from a hanging relay in a repeater/transmitter to even manmade noise. From your recording it's simply impossible to know.
I hope this explanation helps.
Keep enjoying our beautiful radiohobby.

The AlexLoop Walkham antenna is rated for 20 watts SSB max, and the photo of the Traveling Loop shows a variable capacitor with a plate spacing much wider than yours, so you will be very limited in transmitter power.

The KR1ST loop uses a 2 section capacitor both sections in series and with each section measuring 6-32 pF. So the small FM antenna sections would be suitable, not the larger AM sections. To wire 2 sections in series, connect one lead to one of the small plate sections and the other wire to another small plate section, and no connection to the frame. Note that putting two equal caps in series doubles the voltage at which arc over occurs, increasing max transmitting power.

From: thinkdx
Topic: 10306 Message: 10306

Other members of the Loop Antenna group might be interested to hear the audio of some of the medium wave stations I logged with a small (6-1/2 X 4 ft.) rectangular ALA100M Wellbrook loop.
Below is a link to a folder with 13 audio clips from the recent DX trip to Oregon's Rockworks #4
<https://maps.google.com/maps?q=oswald+west+state+park+oregon&hl=en&ll=45.743539,-123.958247&spn=0.005458,0.012392&sll=37.6,-95.665&sspn=49.7388\99,101.513672&t=h&z=17&layer=c&cbll=45.743584,-123.958367&panoid=n-NAZbU\E4n6GYGcgIshWdw&cbp=12,162.05,,0,0.37> cliff:
https://app.box.com/s/ 65z3ei2zz8sep46i37od
<https://app.box.com/s/65z3ei2zz8sep46i37od>
The folder also includes a text file of the complete loggings, and more description.
The range of power of the DX catches run from 10 kw JOQG Morioka / 20 kw JOHK Sendai, to 750/1500 kw HLCA Dangjin.
The ALA100M antenna was mounted above the roof of my SUV, and the receiver was a Perseus SDR with Jaguar software.
This was my first time DXing at the 400+ foot high Rockworks cliffs above the Pacific Ocean, but the signal enhancement was comparable to other times and places I've DXed from a cliff with rock wall to the east (Cape Perpetua area to the south of Newport, Oregon). The signal levels were very good considering the antenna size, but obviously aided by the fine ALA100M module that excels with smaller loops. When DXing at locations like this where I can't erect my usual choices of phased broadband loops or Beverage antennas, a higher gain small loop like the Wellbrook model can serve very well.
73,
Guy AtkinsPuyallup, WA USADXing from Rockworks Cliff #4,near Manzanitas, Oregon

A good person to ask about this would be Iian M1OOO at the Sidmouth Observatory, he spends most his life tracking solar noise and once had myself and a few others chasing up and down the bands listening to simultanious noise patterns which sounded the same as your recording which he was also monitoring from the observatory, it was quite an interesting excersize, http://www.qrz.com/db/M1OOO, but as Rob says it could be anything realy but I have noticed the same coincadental lifts above 440mhz with voices and tones on the carrier.
Phil

I live close to the Jim Creek Naval VLF station. But I don't think that would cause any interference.
I also monitor VLF for SID (Sudden Ionospheric Disturbance) and Jim Creek (NLK) generates a very strong ground wave on my receiver. I am about 12 miles SW of the station!

On Sunday, November 10, 2013 2:05 PM, phil blast <dj_philonline@yahoo.co.uk> wrote:

It has got so bad lately that myself and a few others who run radio gateways on 446 linked to the internet have had to either switch to tone squelch opperation (like I have done) or have the squelch on the gateway radio set up to nearly max to stop them switching to tx due to the static lift, I reviewed your recording and it does not sound like any of the usual man made interferance we hear on the bands from flouresant lights, pump motors, generators, PLTs or thermostats so more than likely solar or aurora.
Do you live near any military or naval bases that do testing or radar? it could also be that as the MOD are sometimes active around those frequencies.
Hope you pin it down

Phil

Hi All,

I have just posted the second video about my Antenna Tuner with two capacitors controlled by Android and Arduino.
It is still for QRP station.
Thanks to the Alexloop manufacturer idea and feedback, PY1AHD, It was possible to make some improvements on Android interface and Arduino program to make the system more use friendly.

The prototype was presented on Pacificon 2013 in Santa Clara, CA last month.

See this video on youtube e video here: http://www.youtube.com/watch?v=hfnlE1sbnEk&feature=c4-overview&list=UU5DmJR6AakJnYCRQop9Gphw

Hi Lane,

I have used one of these extensively on 10 meters. I love that antenna. You can see a picture of it on my QRZ webpage. (KR7K) I have modeled these extensively and they will work in either polarization. I haven't used mine stretched out horizontally. The antenna is actually vertically polarized this way. It is interesting though since it might be used as a lower profile antenna on 40 or 75 meters mounted lower to the ground. Losses become more of an issue down on those bands though.

I wanted something with a bit more gain than a dipole on 10 but still easy to build I still wanted something horizontally polarized. This antenna fits the bill nicely. It models in EZNEC at about 10.5 dBi of gain over normal ground. In practice I have had excellent results with it. If you havent tried one, its worth the 5 bucks in hardware to build one and string it up in the nearest tree.

Good luck, and 73!

Wade - KR7K

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

10318. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-12-01 14:59:35 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 10318

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

I agree with the other poster, just a basic magnetic loop, simple to build, I used the easy toroidial ring feed for mine as I work mainly qrp which also means the tunning capacitor vanes do not have to be that widely spaced so plenty of old ones out there to choose from, Steve Yates has a good collection of homebrew info for you to start with
http://www.aa5tb.com/loop.html
As for performance, well my efforts supprised me with good results from the UK into mainland EU and North Africa and I am located in a hole, very quiet on receive noise wise and they dont mind nearby objects like walls or ceilings, tunning is a bit if a fiddle when done manualy but you soon get used to doing it by ear and get dam close to the sweet spot, give it a go all you need is a plastic pipe to support, a ring of metal like a bicycle wheel rim or copper tube,an old variable tunning capacitor and one of many types of feed usualy coax but the toriodial ring works realy well for me.
Good luck with it and PS for 80m try googling the 80m frame antenna for your next build! you will love it.
Phil.

10322. same capacitor different loops

Yahoo group: loopantennas (2013 — 2017)
Date: 2013-12-02 07:27:20 UTC
From: Craig F. Simmons
Topic: 10322 Message: 10322

If you could swap the size of the actual loop and use the SAME capacitor would this be possible. In other words if you were to build a loop better suited for say 14 mhz - 228/29 mhz and a separate loop with dimensions better suited for say 7 mhz - 14 mhz, could you use a capacitor with enough, correct minimum and maximum capacitance to work on both antennas. For now lets just say QRP power levels only. I fully understand the losses that occur with the connections and the other problems associated with doing the, just trying to see if there is a capacitor range that is possible for both using just one capacitor. The M??-Loop uses the exact size loop for both antennas they sell, one includes 40 meters (Larger capacitor-Higher capacitance) and a smaller one for covering 10 meters -20, losing 30 and 40 meters (Has a lower range of capacitance). This question cam to mind thinking if everything is not permanent, all connections soldered (Not removable) this would be best! But..... for portable use, you will have to disconnect something, and if you could design a put together frame, with say ideal different size loops using the same capacitor this would be good. One bag of frame items, two loops (Made of something- to be determined) and one frame mounted capacitor that works for both. Looking at the two different capacitors used by M?? loop, if you had a capacitor that would go between 10-12pf (low) and 136-140pf (high) this could maybe cover both. This seems would be something that could be done because as you have a length of conductive material closer to the ideal band you are trying to get the loop to work, the capacitance is more predictable. Say different size loops, swappable and attachable to the same lugs,screws, mounting bolts, SO-239 connectors, whatever you decide to use for connection. If you look at every other "Portable Loop" there is, the connection is always less efficient and a permanent soldered connection. keeping this in mind, can we use the same capacitor, with different size loops to achieve better overall efficiency due to the actual size of the loop being optimized for the attended band(s).

There are some details on the web somewhere but mine used a type 64 toriodial ring (I think) nested in a slot on top of a plastic plumbing pipe mast with the loop through it and had two tight turns of the inner coax through the ring soldered direct to the outer coax shield with the coax running down through the pipe out of sight, and was 49 ohms when measured on 20m with a friends MFJ analyser, from what I have seen its sometimes 1,2 or 3 turns prob trial and error.

That is found by trial and error. I use a toroid for coupling and get a perfect 1:1 with 5 turns on two stacked FT-240-61 cores on a 5 1/2 foot diameter loop. I use 1 inch hardline for the loop material. You might need to spread or tighten the turns. I find that close wound is best for me.

Topic: 10263 Message: 10326

Greetings,

I was again pondering some possible low-voltage RF amplifier designs and I stumbled upon a possible idea for a low-voltage (1.2 volts) wideband (untuned) active loop antenna amplifier. I'm wondering if the idea could work.

Consider a common-base NPN BJT amplifier configured as follows. At RF, the base is grounded by a 10 nF capacitor. At DC, the base is connected directly to the collector. The collector in turn goes through a resistor to +Vcc. The resistor value is adjusted for the desired current. The emitter is grounded, but not through a resistor as is usual: instead, the emitter is grounded through the loop antenna conductor itself. Thus the loop current (which we want to sense and amplify) is flowing directly through the emitter.

Amplifier output is taken from the collector through a coupling capacitor.

Could such an idea work as well as a low-voltage BJT differential-pair amp? The appeal of the above design is its simplicity.

C.F.Simmons from Max vk2tti.
It is possable to use different size loops with one capacitive tune/match sysrem. This idea is used in the MFJ936B loop tuner. I clean the contact areas with a brass brush before each use. Soldering would be better but you lose adaptability. For transmitting purposes the loop needs to be of an optimum length for each amateur band such that the capacitor vanes are in half mesh. For receive purposes great accuracy in tuning cannot be achieved as the signal waxes and wanes making it difficult to tune with precision. This has been my experience. Regards to all vk2tti.

Hello,

I have made some experiments to evaluate the performance of simple 2-element arrays with small wideband active elements - dipoles or loops.

Dear Chavdar,

Thanks for an interesting paper.

I have a few comments to make: There is no provision to amplitude balance the antennas or to compensate for minor delay-line loss. One is therefore assuming that the antennas are always gain matched with frequency even when the presence of nearby objects could be affecting the gain. This will in some circumstances reduce the F/B as nearby objects (metal fences, power/phone line etc) affect the antennas near-field response especially at LF/MF.

My experience with MW active dipole, active loop and active K9AY arrays using variable delay-line and switched delay-line phasing indicate that the provision to vary the antennas gain is just as important as having control over the phasing.

I agree with your observation that a 1 to 10 frequency ratio is readily achievable. However, where the antenna spacing is very small, there is a further degrading in s/n due the amplifier noise not cancelling out in same way as the signal. This is more of an issue with small 1m diameter high gain loop antennas. Also with very close antenna spacing the array phasing and gain balance becomes very critical, causing pattern degradation. Therefore, it may be prudent for MW/LW use to allow for an increase in antenna spacing to over 30m.

Using the above arrays at HF can be quite disappointing due to signals having too much angular variance. Loop arrays offer the worst performance because they offer little rejection of rear high angle signals.

Additional Reference:

Keen's Wireless direction Finding, Third Edition 1938.

Kind regards

Andrew

Hello Andrew,
Thank you very much for your interest in my work.

--------Comment
I have a few comments to make: There is no provision to amplitude balance the antennas or to compensate for minor delay-line loss. One is therefore assuming that the antennas are always gain matched with frequency even when the presence of nearby objects could be affecting the gain. This will in some circumstances reduce the F/B as nearby objects (metal fences, power/phone line etc) affect the antennas near-field response especially at LF/MF. My experience with MW active dipole, active loop and active K9AY arrays using variable delay-line and switched delay-line phasing indicate that the provision to vary the antennas gain is just as important as having control over the phasing.

---------Answer
You are right - there is a gain variance. As shown on Fig.18 the signal difference between two antennas depends very much from electromagnetic environment it is up to + - 3 to 4 dB in bad conditions and less than 1 dB in clear place. And moreover it is frequency dependant. The loss in the delay line is usually less than 0.5 dB. Usually the gain of the amplifiers is not the problem (with 1% elements the difference can be set to be less than 0.2 dB). As you say the problem is the environment. But any precise gain correction is frequency dependant so changing frequency you have to change the gain correction. Probably with analogue phasers you can set precisely the best gain and phase and to increase the F/B. But this is time consuming , frequency dependant and for me not very practical. I do not think that it is so important to have let say 13 dB instead of 10 dB F/B on real signal. We must swallow the reduction of the F/B for the price of increased functionality and real wideband performance. In the case where the array is built in a clear environment such a correction is not needed. From the experiments you can see that without such corrections the F/B ratio can reach 45 dB in controlled conditions.

--------Comment
I agree with your observation that a 1 to 10 frequency ratio is readily achievable. However, where the antenna spacing is very small, there is a further degrading in s/n due the amplifier noise not cancelling out in same way as the signal. This is more of an issue with small 1m diameter high gain loop antennas.

---------Answer
Yes, I have pointed out that in very closely spaced elements you should have to use larger elements to improve the noise floor. See 5.5. in discussion part.
--------Comment
>Also with very close antenna spacing the array phasing and gain balance becomes very critical, >causing pattern degradation.

---------Answer
I do not think so. See 5.4, In very closely spaced arrays the main problem is the reduction of the effective height and the noise floor limitation, the optimal phasing is easily

obtained at least with controlled delay line. You can look at Fig.8 where the sensitivity to 20% deviation from the optimal delay is plotted. The pattern, at least in models, is not degraded down to very small D/wl. I can not say how is influenced the pattern in real environment – this will be very difficult and time consuming experiment but in my controlled experiments the F/B is not much degraded even below 0.05 D/wl. Look at Fig. 16, Experiment 3, where F/B ratio is plotted. For 1.8 MHz and D= 6m (0.036 D/wl) the F/B is between 25 and 35 dB for both loop and dipole arrays.

--------Comment
>Therefore, it may be prudent for MW/LW use to allow for an increase in antenna spacing to over >30m.

---------Answer
Yes, The optimal distance D is somewhere between 0.1 to 0.25 D/wavelength. That means for 1MHz, D is between 30 and 75 m . But my main question is how to squeeze D in order to build very closely spaced arrays which are still usable. I am pretty sure that with careful antenna design and proper amplifiers and matching we can reach uncompromised performance with D/wl values equal or below 0.05. For spaces 0.01 wl and below I suppose that the additional problems will be common mode signal leakage and probably the reactive filed influence between elements.

--------Comment
>Using the above arrays at HF can be quite disappointing due to signals having too much angular >variance. Loop arrays offer the worst performance because they offer little rejection of rear high >angle signals.

---------Answer
I do not agree. If we expect the behavior of several element yagi of course this is not the case. But the 2-el loop array has decent directional pattern and it is the best RX antenna in my small yard. The 2el- short dipole mode is influenced too much by nearby cables and the metal fence and has too high noise from nearby high voltage electrical line. Practical comparisons to K9AY loop show that the directional characteristics of the 2el-loop array are definitely better (at least in my yard). The loop array has also narrower front lobe compared to the dipole (vertical) array. From the other hand in clear environment using loops and dipoles with the same switching scheme and delay setup is an advantage – it is always better to have 2 antennas with different patterns.

--------Comment
>Additional Reference:
>Keen’s Wireless direction Finding, Third Edition 1938.

---------Answer
Unfortunately I do not have an access to this paper. Some times I have a feeling that I am inventing the wheel again. I am pretty sure that a lot of work has been done in this field in 30’s upto 60’s years of 20th century. I am not professional in this field and I have done this work to satisfy my own curiosity.

Kind Regards,

Chavdar

Hi Dave,
I will repost picture/s of the loop head I made for the Ramsey Signal Magnet.
Not sure what happen to it. Long ago, Steve, the moderator suggested putting pics in the files section for better resolution. That may not be the case anymore.. So it will appear in the photos. My latest head is comprised of Everett's Stacked Toroid Loop for LW/MW and is used on a Palomar base. It truly amazes.. For the message that attended the Ramsey photo, see post #655. Reception was made adjacent to a high tension transmission line as well!

Thanks John,
I hope this hasn't been an inconvenience. I just assembled the Ramsey antenna and like most of us I have to see if I can improve it. I have a bunch of rods similar to the one in the Super Magnet and thought about bundling several of them and winding with Litz wire instead of the magnet wire that Ramsey supplies in the kit. May try putting two or three end to end. Thanks again. Dave K2ZU

Dave,
I posted the pics of my old Ramsey shielded loop from '05 plus a couple of later creations in my John's Stacked Toroid Loop photo file. They are a final version of my Stacked Toroid Loop as a Palomar amplified loop head and a 7.5" FSL. Both designs from Everett Sharp. Both work extremely well on LW and MW. Litz would probably help the Ramsey as well a close winding it as well..

John.

Date: 2013-12-13 23:53:07 UTC
From: <kc7nj@...>
Topic: 10339 Message: 10345

I see why I couldn't find the files. I was looking for John Stumm not Lowalacrity. Thanks for the info. I tried putting 8 inch rods end to end on both ends of the Ramsey antenna and it makes a LOT of difference in received signal level.
The antenna will be about 26 inches long with the extra 8 inch rods but will still work ok from a parked car. I was using a 3' square loop but it's too much trouble to set it up and take it down.
Funny thing about the Litz wire. I thought the Q would be greater and the tuning sharper but the tuning doesn't seem to be any different except for the shift down in frequency due to the increase in inductance. I'm guessing the Q is sharper but I don't have a simple way to measure it.
If I manage to make enough of a difference that enables me to hear Martians I'll let you know. Dave

Date: 2013-12-15 06:14:11 UTC
From: Chris Waldrup
Topic: 10347 Message: 10347

Hi,
I am building up the KD9SV preamplifier using the circuit board and having loads of trouble with oscillation is the gain pot is turned much past about 30 percent.
I'm testing it on the bench and feeding 1850 khz out of my 8640 generator into the amp and the amp is terminated with a 50 ohm load. I am looking at the output with my scope probe (10x) across the load, and the unit is oscillating in the FM broadcast band as seen with the frequency counter connected to an output of my scope.
I tried removing the flux around the dual gate MOSFET (using NTE455) package thinking that might help but it didn't.
Has anyone else built this, and if so did yours work initially?

Thanks!

Chris

Topic: 10350 Message: 10350

I have two of the AAA-1B active antenna amplifiers that I got from LZ1AQ
These have both been only slightly used and come with all the extra parts. They both work and look as new.
The price new was about $120 shipped. I would like to get $90.00 each, shipped in the CONUSA. PayPal preferred.
These are very nice active amplifiers and they work very well. I have just changed directions so I no longer use them. I used them with small copper loops and got very good performance from them.
Thank You
Larry Naumann n0sa

From: <k910dog@...>
Topic: 10352 Message: 10352

Anyone looked at making butterfly capacitor kits from copper. The weld that MFJ used to attach their butterfly capacitor to their aluminum loop is a great concept but we all know that copper is better conductor, and if we could braze/solder the connection of the butterfly loop directly to the copper loop (Homebrew) this would be a lot more efficient.

Good question. I have quite a few DMMs with built-in capacitance measurement, including several Flukes at work. The lowest scale on all of the ones I've used only go down to the nF scale, down to one pF (0.001nF).

I used to build and sell capacitance meters. Originally with a standard 50uA meter for the display, then I built them to use any DMM as the display on the 200mV scale.

Here is a schematic, for best results us the TLC555 (CMOS version):
http://www.polyphoto.com/tutorials/ElectronicCircuits/Dual555CapMeter150dpi.jpg

It does require a regulated voltage. A 78L05 works fine, or pretty much any modern well-filtered switching regulator. It wasn't meant for measuring large capacitors, so the largest capacitor it will measure is 20uF on the 2uF scale when your autoranging meter switches to the 2V scale.

I still have one. I built one ugly on purpose so I wouldn't/couldn't sell it. It easily resolves 0.1pF pretty stably. Keep in mind that with any measuring system, resolution is not the same as accuracy. I have a 0.1% capacitor I use to calibrate it on the 2000pF scale, and trust the tolerance of the other resistors.

I now have a Honeytek A6013L digital C meter, range: 0.1 pF to 20000 microFd bought new on ebay. I like it, but I cannot really comment on its accuracy. So far, for me having capacitances read from it is better than capacitances from my old Heathkit RLC bridge. Bill Young WD5HOH

~Anyone looked at making butterfly capacitor kits from copper. The weld that MFJ used to attach their butterfly capacitor to their aluminum loop is a great concept but we all know that copper is better conductor, and if we could braze/solder the connection of the butterfly loop directly to the copper loop (Homebrew) this would be a lot more efficient.

Copper is quite soft, easily bent, and difficult to de-burr. I would use thin brass for capacitor plates for its easier working and polishing//de-burring properties. It solders very easily, and I suspect that its conductivity is so close to copper that “there’s not enough difference to make a difference”.

Cheers,

Brian Burns Ex: W5BRO, K6UCD

See my website: www.lessonsinlutherie.com

Considering that the starting point was Aluminum and the change to copper was to improve the conductivity, then yes, Brass has a lower conductivity and *will* make a difference. The resistivity of these materials in nOhm m are

Cu - 17.1
Al - 26.5
Brass - 64

Of course the composition of Brass varies a bit and so will the resistivity, but it won't change enough to alter these relative amounts.

In changing from Aluminum to Copper, I would question the resistance of the soldered connection compared to the solid body of the Copper. It may well be that the added resistance of the welded Aluminum is less than that of the soldered joints. Solder is *much* better than mechanical connections, but I expect a weld is significantly better yet. However the devil is in the details... just how good a solder joint you get.

Anyone have an idea of the relative resistance of the antenna materials to the radiation resistance? Wouldn't that be what determines when you have reached a point of diminishing returns in optimizing the material resistance?

Rick

I use both the SmartTweezers ($350, but really slick) and the AADE Model iIB ($99 kit). The AADE will measure L and C very stably and I carry it to hamfest tailgates. Get the 3/4 inch binding post spacing option - it fits standard banana jack spacing. See it at www.aade.com.

The SmartTweezer also gives you Q and ESR. It's a bit more precise, but the AADE's 1 to 2% is fine for most of the stuff I do :)

Yes. If I was doing one in brass, I'd be silver-plating all the components before final assembly, then using silver solder. That would give you a nice high-q capacitor.

Hi Fraser

just once more browsing thru DX-one threads...: apparently you are in possession of Xrays! Could you please forward copies to my email address ulrich.ruch@gmx.ch mailto:ulrich.ruch@gmx.ch. My headamplifier has been laying around defective for more than one year, and all my queries at RFS remained unanswered. I would therefore like to have it repaired by some local - but for this I need to know how to get access to the amplifier resp. how disassembly is made without causing any damage to the rest of the antenna stub.

Looking forward with keen interest to Hearing from you.

73s and happy New Year

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

10362. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-01-01 14:25:28 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 10362

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

I had a DX-One (MK2) for about two years. It worked very well but my HOA made me take in down and I ended up selling it.

1) It is ABSOLUTELY an omni-direction vertical.

2) It was the best vertical I had ever used and I had most of them. I now have a DX Engineering active whip because it is lower profile. I would say it has 80%+ of the performance of the DX-One at 25% of the price. Where the DX-One REALLY excelled was in the LW band where reception was significantly better than with any other antenna I ever used.

3) I seem to recall that the developer (and President) of RF Systems died earlier this year. My understanding was that the company was no longer in business though it seems Universal Radio still carries their products.

> I just deleted that earlier PDF file and replaced it with "Active Antenna Amplifiers for Low Voltage Operation.pdf" that has the low input impedance amplifier on the second page. This is still a work in progress.

I'm thinking about building the low-input-impedance amplifier on the second page, using 2N3904 transistors and running off of 1.2 volts. Intended use is for shortwave listening and maybe MW listening. A couple of questions:

1. Are the ferrite beads necessary?

2. I'm thinking about winding the inductors and transformers as follows. All inductors will be wound on FT50-43 cores. T1: 20 turns, center-tapped. T2: 20 turns primary, 20 turns secondary, each center-tapped. L1: 20 turns. T3: 20 turns primary (center-tapped), 20 turns secondary (output). Do these values sound reasonable?

3. For Q1-Q4, what base and collector voltages should I aim for?

4. Is symmetrical physical construction important?

5. Why can't we take the antenna output directly off of the T2 secondary, using Q3 and Q4 only and eliminating Q1 and Q2?

6. I'm planning on using the coaxial cable to supply power to the antenna, using a bias tee and running +Vcc through the T2 secondary (similar to the original M0AYF design). Any problems with this approach?

Thanks for any advice.

Ian,

Did you by any chance have a Wellbrook 330S or 1530S in the past collection of antennas you could compare the RF Systems to?

Thanks,

John

Unfortunately not John. I do have a Pixel Pro 1B now. No comparison, the DX-One was WAY better. In fact I think all in my DX Engineering Active Vertical is better than the Pixel as well.

Maybe I am just lucky because this is a pretty low noise QTH but here at least the only thing I get out of the Pixel is directionality and that's just on BCB. The overall signal levels on the Pixel are a few db lower than the vertical on anything above say 3 MHZ. Not awful / unreadable but lower than on the vertical and of course there is virtually zero directionality on skywave.

I guess if you lived in a noisy environment a loop would be much more beneficial but it hasn't been here, Perhaps a Wellbrook would be better but there seems to be no consensus on that. Guy Atkins' tests point to the Wellbrook, Jack Smith's to the Pixel and both of those guys are knowledgeable, creditable sources so maybe its a QTH specific thing.

JMHO.

Hi Steve,

I used a version of this circuit many years ago as a relay-switched preamp for a homebrew communications receiver, and it worked extremely well ahead of an SBL-1 mixer.

It's essentially cribbed from the "Omega" HF transceiver design by G3WPO and G4JST, which was published in the UK in the mid-80s in the now defunct "Ham Radio Today" magazine. It might be nice if SV1AFN acknowledged this sometime...

A nice design, though, and the SMD implementation is very neat.

Regards,

Dave

The website doesn't mention the input impedance of the amplifier, but it looks like it is fairly high. This is not optimal for the loop, which works better when loaded with a low impedance.
You can read excellent articles by Chris N7ZWY in the files section of this group to learn more about loop preamps.
This amplifier may be more suitable for a short whip.

Yes, it's more suitable for short whip (monopole) antennas that require a high input impedance amplifier. Loops have a very low terminal impedance, so a balanced common-base amplifier is more suitable. I have a fairly rigorous one in the files section, and a simpler one was mentioned here recently.

Low noise preamp for wideband loop

Friends im searching for a very low noise wideband loop preamp,
is for use in areas with very weak Mw signals, my loop is a 3mt
diameter wire loop and im testing the preamp with two 2n2222.

this preamp have noise in order the signals i want to receive, the
preamp can receive it, but adding a strong noise floor

Here the loop, in past year DX-camp in a remote farm in patagonia Argentina

I just uploaded a revised version of my sketches of low-voltage active antenna amplifiers into the group files section:

Active Antenna Amplifiers for Low Voltage Operation RevA.pdf

They are oriented towards 1.5V applications, but can be used at higher voltages. The first two schematics require that the transistors be parts of a monolithic array, such as the CA3046 or HFE3046. The third schamatic includes feedback for correcting the imbalance when using unmatched transistors, such as individual 2N2222s.

10387. Questions from the archive and files section.

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-01-10 02:07:57 UTC
From: Ben Hall
Topic: 10378 Message: 10387

Good evening all,

I'm kind of new here so I have been been reading some of the posts in the online Yahoogroups archive.

I recently built a Mobius loop per Chris Trask's instructions in "Mastering the Art of Shielded Loop Aerials." It works *very* well with the remote varactor tuning, but I would like to try it with a pre-amp in a broadband fashion.

My interest in the loop is to try my hand at receiving LOWFERS, NDB's, and some of the transmissions around 500 kHz.

In reading the archives, I'm trying to find more information on two topics.

First, a post makes reference to a "modified M0AYF amp." In another message there is the statement "Guys, I found that this modified M0AYF amp works much better than the IZ1AG (LZ1AQ?) amp."

I think there was a link that originally followed, but thanks to the awful new Yahoogroups interface I believe it has been stripped out.

Please forgive me if this is easy to find in the archives. I about went mad searching the archives online, I would search for a topic, get a return that looked promising, click on the message and the message loaded was absolutely NOT the same message in the search results! (Thank you Yahoo...)

So...can someone please point me towards the modified M0AYF amplifier?

Second, reading Everett Sharp's (N8CNP) article in the files section on building and evaluating broadband active loops, there is a mention of a modified Kits and Parts Wideband RF Amplifier.

I'm not clear on two things:

- Is the amp fed from the loop via the 1:2 matching transformer?

- Was the Kits and Parts amplifier evaluated on the Mobius loop?

If yes, what was the ground on the pre-amp connected to? I understand in the shielded coax loop it was connected to the shield, but in the Mobius configuration, due to the cross-over at the top of the loop, what is the equivalent of the shield braid?

(Also, if Everett reads this message...my grandmother's maiden name is Sharp, with the story that when her parents came to America, it was changed to Sharp from Skorupski so they would sound more American. If

this strikes a bell, we're probably related.)

thanks much and 73,
ben, kd5byb

Hello Ben,
In your recent mail you asked:

"So...can someone please point me towards the modified M0AYF amplifier? "

Well the schematic shown in Everett Sharp's mails is the modified M0AYF. You can find the original in:
http://www.qsl.net/m0ayf/active-loop-receiving-antenna.html

From: <kc9q@...>
Topic: 9604 Message: 10390

Hi Danny,

Here is a link to a core calculator application:
http://www.dl5swb.de/html/mini_ring_core_calculator.htm
http://www.dl5swb.de/html/mini_ring_core_calculator.htm

Go to the Iron Powder Torrid TAB. Then select the Material Button (right of the Core Size (i.e. T50). As you change the Core Material the applicable frequency band will show to the right in the Frequency Range box. Also the color code will change according the to Core Material, and at some point the color code will go from a single color to a dual color band.. You'll also get more information about your core with this app. (Note: For transmitter applications Ferrite Core are preferred. Iron Powder are OK for receive only applications, IMHO).

73,
Mike< KC9Q

Danny,

I added a link fir the mini Core Calculator app in the Links folder under the ferrites sub folder. Tab to the Iron Powder Torrid menu, and then select different Core Materials. This will provide you with the different color codes and Frequency Ranges.

Mike, KC9Q

10395. Horizontal Loop Antenna For Digital TV

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-01-14 04:50:56 UTC
From: <gregella53@...>
Topic: 10395 Message: 10395

I was recently reviewing online designs for homemade DTV antennas. Most of these designs are for UHF (channel 14 and up) and are of the general design of multiple V dipoles with a phasing line, in front of a reflector screen. These antennas are directional, and have to be aimed at the transmitting tower. In my particular location, rural open space with no multipath problems, I wanted an omnidirectional antenna (or at least one with 180 degree coverage) that covered VHF high 174 MHz up through UHF.

Searching through Internet postings for omnidirectional DTV antennas, I found a couple of descriptions for horizontal loop antennas. THese have been constructed of 1/2 or 3/8 inch copper tubing, in a horizontal loop of about 26 inch diameter, feeding a standard television 300 to 75 ohm balun and coax cable. They are typically supported with a horizontal PVC cross and mounted outside on a roof. In one design the loop is a complete circle except for a gap at the feed point. In another design there is also a gap 180 degrees across from the feed point.

I tested this design by picking up a slightly damaged aluminum bicycle rim (about 22 inches diameter) for two dollars at a used bike shop. I cut out a one inch gap and attached a balun transformer with two screws through existing spoke holes. I tried this antenna indoors horizontally on a table next to a large window, and picked up 14 digital channels, both VHF and UHF. Based upon the signal strength meter in the TV, this antenna was omnidirectional on some stations, and semidirectional on others. On those channels where there was some directionality, it seemed to favor the feed end of the loop. It still had a wide beam width on these channels, though.

I made a second horizontal loop out of heavy wire so I could test the effect of a gap 180 degrees from the feed point. This increased the signal strength on some channels, but caused me to lose other channels, so I only got 11 instead of 14.

The aluminum bicycle rim is cheap, rigid, rustproof and easy to come by. It will be easy to mount horizontally outdoors, where I expect it to perform even better. This might be a good platform for other loop antenna projects as well.

DTV receivers do not handle multipath well, so this would probably not be the best antenna in an urban environment, but for a more open area with various towers in different directions, it seems to work well.

You cannot link to a file in that way, Yahoogroups provides a temporary link that only works for 20 minutes at most.

This is a message for all: Please do NOT use high ASCII characters in file names. I cannot make a link to the file now, and I am also unable to change the name or delete it so I can reupload after renaming.

I did finally find a workaround.

In future, please post files with names in English so as to avoid all high ASCII characters, and if it is a file on a website, please post a link rather than uploading it. We have only 100MB of file space. I just had to spend a lot of time cleaning out the Files area on another list.

Here is the company that the PDF came from:

10405. Cannibalized Super Three Rod

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-01-23 14:54:17 UTC
From: <dr_seamless@...>
Topic: 10405 Message: 10405

OK. I posted on this a few months ago but cant find original post so I'll do again.

I've got a super three rod mounted in a plastic box. Attached in parallel is an L type attenna tuner like an MFJ. I've wrapped a few more turns around the center of the rod and coupled a trimmer (fixed) cap which I took from the super three board across the output. It resonates proper up to about 1 MegHz but above that tunes only on strong local stations. I'm testing on weak daytime stations and it works well on 910kHz with some added inductance from the antenna tuner but at 1240 it's very weak with no added inductance. I have more trimmer caps of different colors that I can cannibalize from the super 3 board but don't know how to adjust them or what values the colors represent. They look very fragile like an adjustment might break them. The one I'm using now is white. Would adding another trimmer cap across the output move the bandwidth up, or would it lower the freq?

10406. MFJ 1788 SWR readings

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-01-26 01:26:38 UTC
From: <ve3wdm@...>
Topic: 10406 Message: 10406

I had some odd SWR readings and not sure why, the antenna is not located in an ideal location. I have it on my balcony 6 floors up below are the SWR readings both good and bad.
40m at 7.049 the SWR was 1.8.1 which is great and I have no problem with the results.
30m at 10.132 the SWR was 2.2.1 not great but it's the lowest I could get.

20m at 14.049 the SWR was 11.7.1 and the SWR never moved from this reading and I found this very strange an not sure why?

17m 18.104 the SWR was 1.7.1 and then I moved to another band and when I returned to 17m and same frequency I was not able to turn back to 1.7.1 The SWR was 13.2.1 and never moved just like on 20m.
15m at 21.060 the SWR was 1.1.1 and I have no problem with that.
10m at 28.035 I was not able to get the SWR below 6.4.1 it stayed at this SWR through out the whole tune process.

Not sure why the SWR is behaving this way on 20m, 10m and then once good on 17m and then the same as 20m and 10m with a high SWR and not moving.

Hi - Include a picture looking at the building where the antenna is
located. It may give us an idea
of what might be causing your antenna detuning.

Today I took the 4 foot tunable loop antenna down and am in the process of putting up a "Low Noise Vertical (I hope ;-)

I put the loop up in 2012 as an experiment in the hopes that I could null out interfering beacons and add to my beacon score. It was a big disappointment though. Yes, it did pick up beacons OK, but the nulls were very poor. I first tried connecting the fet pre-amp to the high side of the tuned loop, but for all practical purposes there were no nulls. I suspect that the "antenna effect" of the unbalanced loop, along with environment (just above a sheetmetal roof) was the main problem. Later I disconnected the pre-amp from the high side of the tuned loop and used a single pickup turn to the pre-amp. Yes, there was an impedance mismatch, but that shouldn't have affected nulls, just the gain. The "Q" was high as the varactor tuning was very sharp. . .

Well, that worked better, I could get shallow nulls (around 10dB or so) on some beacons, but not others. Not good enough to sneeze at, or even to actually use the thing as the "active whip" could hear most of the weaker beacons much better.

So today I took it down so that I could install a 30 foot "low noise vertical" (I hope) in it's place. I figured that I'd offer to GIVE the loop to somebody IF they wanted to experiment further with it. Well, that didn't work out! As soon as I lifted it and the rotator off the push-up pole it got away from me and went crashing to the ground some 15 feet down! The result was a crumpled mass of PVC pipe and tangled copper wire. The thing literally came apart at every glued & screwed joint! It landed top side down and the weight of the rotator and metal TV mast probably didn't help preserve it any.

Anyway, after that little escapade I went ahead and installed the vertical section on the top of the Push-up pole. It consists of a Hustler MO-3 mast section (aluminum) with an 80 Meter resonator and stinger mounted on it (I figure that the inductance of the coil MIGHT help a bit). That is mounted on top of about a 7 foot piece of 2 inch PVC pipe, sitting over the top of the push-up pole. There is a 20 foot section of 5 conductor 18ga rotator cable coming down at an angle from the bottom of the Hustler mast to an insulator at the roofline of the mobile home (angled to get it away from the metal push-up pole. The total length is right at 30 feet and gives me a 30 foot vertical above the roof. The matchbox containing the toroid (about 80:6 turns or so) will be mounted right at the roofline and provide the balanced output running into the radio room. The primary side of the toroid will be grounded to an 8 foot ground rod separate from all the station grounds.

Tonight I'll wind the toroids (80:6 antenna section and 1:1 turns in the shack), put them in suitable housings, and hopefully install that tomorrow. I'm to "bushed" to do any more today. At 70 I'm almost too old to be running up and down ladders and shoving those poles way up in the sky, lol!

The toroids I'm using right now. They're "unknowns" from a switching PS, seem to work well at LF, but later I'll purchase a couple of new ones with known characteristics. It won't be too hard to change them out at a later date.

I believe the balance of a small loop antenna is indeed the key to get its figure-8 pattern with the nulls. That, along with the metal roof might explain why yours didn't show any, and why it got at least partial nulls when you changed to a separate coupling loop.

Andy

10416. Trask Amplifier for Wideband Active Loop Amp - mod suggestions?

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-01-29 12:26:58 UTC
From: Andy Gardner
Topic: 10416 Message: 10416

Hi Team,

I'd like to try out one of these amplifiers on a 1.8m aluminium loop I have built. Not sure if the designer Chris Trask himself has time to answer questions right now, but I thought I'd put them out on the mailing list in case anyone else could answer as well, and others might be interested in the answers anyway.

The loop I have built has the feed point at the top, and the balance point at the bottom is grounded to earth. It's up that way to get the business end as far up as possible. The bottom part is actually strapped to an alloy pole that is clamped to the centre pole of the old rotary clothesline out the back of the house. Hopefully that's fine, although she who wears the pants isn't totally impressed because it removes the "rotary" function out of the rotary clothesline.

I'm getting fairly good results with the lz1aq amp I have installed at present, but have IMD problems with BCB stations. I'm interested in 0 to 30MHz, so would rather avoid a BCB filter. The plan is to orientate the loop so the 2 local AM BCB transmitter sites are sitting in the null. (~90 deg at 2km and ~60 deg at 5km)

But my feedline I use is a run of Cat 5 ethernet cable, with one pair carrying the signal and the other 3 pairs sharing the +V and 0V load. So I need to reconfigure the amplifier's T6 output transformer for separate power feed, and balanced 100 ohm coming out.

Suggestions gratefully received.

Andy

It's actually fairly simple, and can be accomplished with a few modifications. First, break the connection between T6 and C20, then connect your power line to C6, Q6, etc. to complete the supply connection. Done.

Looking at the output side of T6, break all of the shown connections. The upper terminal of the upper winding is your + output, and the lower end of the lower winding is your - output. Connect the lower end of the upper winging and the upper end of the lower winding to ground. Done.

The collectors of Q3 and Q4 will now see load impedances of 200 ohms instead of the original 400 ohms, so the power gain will be reduced by 6dB.

Thanks Chris!

Hopefully the 6dB reduction won't be too much of a penalty. I would have to go to a different design for T6 to get the gain back?

Cheers,

Andy

Not easily and it wouldn't be worth the effort, but you could add an additional 3:2 autotransformer after it that would raise the collector load impedances to 450 ohms, which is reasonably close and would actually raise the gain by about 1.0dB. I don't have a drawing set for that readily available as I've never had to describe one, but it's fairly simple.

What is the lowest capacitance on one of your kits, along with the max. I keep seeing the highest being listed but nothing about the low end. This is important to me because I have one loop that works great on 30 meters and 40 meters but just lacks a going low enough to cover it. Both valuse would be great to know if possible. And yes I know if I make the loop length shorter that will change what is needed. This will make it easy for me to order a few kits. thank you

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1. * Justice AM Loop Antenna (Active)
> - - - discontinued
>

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

10425. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-02-01 12:45:46 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 10425

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

10426. Question About Tuning Diodes

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-02-02 02:28:41 UTC
From: <nick.nickrumple@...>
Topic: 10426 Message: 10426

Hi All..... I have a question that I hope someone can help me with. I am planning to build an outdoor remote tuned loop antenna. I have read that you can find tuning diodes in the range of 40 - 700 pF. Does anyone have any experience with such diodes, and if so, where may I find them. Where I live, there are no electronic parts stores, so I will have to order them. Thanks in advance.

I've done a number of remotely tuned antenna designs and the varactors I like to use have been the MVAM109 and MVAM115. But, those and their direct replacement, the NTE618, are difficult to obtain and pretty expemsive. The 1SV149 is currently available for a very low price in eBay (#200609638692) and has been used by a number of people as a substitute.

I would not use LEDs as varactors. The LEDs act as photodiodes to some extent, generating noise.
It's better to use a zener diode, if you have to.

I have a Pixel loop that I want to put at the back of my 20 acres
fed with a 1000 foot length of coax. I tried to ask the factory
about that, and got a confusing answer. You need to address this
issue.

I came face to face with one of these last week at the local candy store (HRO). Nice looking. Impressive up close.

I should have asked them if they have it hooked up to one of the demo rigs. The online video is one thing, hearing it in person is another.

For me the price would be a real issue. Anyway I'm not in the market for one.

Pretty pricey, but if I didn't have DIY skills, I'd certainly be looking at one.

What the use of spending $800 odd dollars on a comms receiver, and feeding a noisy signal into it? You'd be far better off buying one of these and spending less on the radio itself. Unless you enjoy listening to QRM.

As they say - garbage in, garbage out.

It comes with a "brick" style amplifier made by Clifton labs.
This is a high quality design with good large signal handling
and a 3 dB NF. Being connectorized, I can use it for other
antennas. I like having it around for a general purpose preamp
for experimenting with other receive antennas. With 30 dB
gain, it can drive my 1000 foot coax line to the back of the
property.

Anyway, the amplifier is worth a fair amount of money in its
own right.

Topic: 10432 Message: 10442

So, Dominique, you've tried them both and prefer the Wellbrook - or you interpret Guy's data and agree with his conclusion? Go to Pixel's site and you'll find the Pro-1 beats the Wellbrook. I wouldn't expect a commercial site to use an unflattering comparison in their advertising.

I certainly have built my share of antennas - TTFD, slopers, dipoles bi-Beverage, long wires - active antennas - even remotely tuned/amplified balanced loops. I have a technical background - got my FCC First Class Radiotelephone license 9/68; was a USN ET ('69-'72); taught electronics/telecommunications '75-'95; and chiefed at several FM stations and part-time at one AM station. Why would I spend most of $400 on something I could build? In retrospect, that decision three years ago was a good one.

I bought my Pro-1A three years ago to replace my wire antennas, whose ancient tree supports had succumbed to disease and/or the ravages of weather, the worst of which was destined to test the Pixel antenna 4/2011 & 1/2012 in two tornadoe near misses. The first one dislodged some roof shingles, as it was airborne here, but the second one turned the loop as it emptied the deck the antenna was mounted to and redistributed my wife's wind chimes, totally destroying homes a block away. I had chosen the Pixel for it's robust and modular construction - and it had paid off. Having been 'made in the USA' didn't hurt, either. Last summer found my wife and I moving - after 36.5 yr - to a garden home.

The new home has a Home Owner's Association - with by-laws prohibiting outside antennas. I carried my Pro-1A up the stairs to the floored tall attic and mounted it's 5 ft mast in a tripod mount and set it high and as clear of interference as I could, hooking it's RG6 feed to an existing such feed to my 'office' below. I now have the best and most QRM-free reception I've ever had. The background noise is minimal - and the desired signals are stronger than I recalled at the old house 3 miles away. The background noise is practically non existent, from the 200 kHz remaining aeronautical beacons to MW BCB stations to tropical bands to SW BCBs, as sparsely populated as they now are. It's directional nature permitted reduction in a QRM source - the metal cylinder in my yard (buried utilities) which contains the fiber optic/twisted pair DSL modem was DFed with my Tecsun PL-660 as the culprit. In all honesty, protected from the elements - in my attic - the Wellbrook would have been fine.

I spent most of $400 on my Pixel simply because I had it - returns from another hobby-item's sale. I don't regret it one bit - it and the R30A - resurrected my longtime hobby. I even got my NRD-525, R8, & HF-150 out of storage and since bought a used R75 and HF-225 - all sharing the Pixel antenna. One minor regret, born from my prior experiences with power outages - no 12V power inserter for battery power. I can remedy that after I find my soldering iron! If you've never tried a decent shielded loop antenna, you need to. Whether you build or buy is up to you.

John

Hi John,

Interesting thread indeed !
Yes, I tried them both and then I read Guy's review. My conclusions fully match with his.
My QTH is 12km / 7miles from a LORAN-C transmitter (LESSAY/Normandy/France) which spits out 250kW on 100kHz from a 250m high tower 24 hours a day. Hence, I suffer from considerable antenna/receiver overload and IMD issues.
I've been looking for a long time for receiving antennas which can stand such harsh conditions and can feed my receivers with very clean signals (I think I already tested all existing active and magnetic antennas except those from Rhode & Schwarz - a bit too expensive for me -!).
I had heard that the PIXEL RF Pro-1B is a must in the magnetic antennas world and decided to buy and test one. I compared a brand new PIXEL Pro-1B side by side to my 5 WELLBROOK loops (ALA1530 (2x), ALA100, ALA100M, LFL1010) in early 2103. The WELLBROOK loops ALWAYS were the best ones in terms of sensitivity and especially concerning the S/N, not only in the VLF and NDB band: from 125kHz up to the HF bands no trace at all of the LORAN-C's rattle and no noise, far better S/N ratio on the HF bands than the PIXEL(e.g. constant S3 on 2182kHz with the Pixel, S0 with the WELLBROOK loops) !
I can confirm Guy Atkins conclusions: WELLBROOK beats PIXEL in every configuration ... not only in terms of price !
Like most other Pixel users here in Europe I sold on my RF-Pro-1B after one month use.
Now the last, but not the least: WELLBROOK's boss Andy IKIN is very customers-friendly, he provides help and advices rapidly and at any time !
Nice product and nice after-sales-service: I can only recommend WELLBROOK !
Hope it helps

Dominique
Normandy, France

PS I don't have any connection to this company !

I think the problem for UK and European users is that the Pixel can cost $700+ landed due to the shipping and the inport duties/tax etc.

Regarding the reviews, the one on the Pixel website compares their loop with the 1530L which is a variant of the standard 1530 designed to work better at lower frequencies rather than high. It does not compare apples with apples.

Re battery backup of the Pro-1 loops ...

The power coupler supplies 20V DC (nominal) to the coax, and is normally powered with a 24V AC (RMS) transformer. It is possible to replace the transformer with a floating DC source such as a battery, but it will need around 26V DC. A pair of 12V gel-cell batteries in series should work.

One could try a 12V-120V inverter for battery power, but from theoretical considerations it would need to be a sine wave or at least a modified sine wave inverter. And, there is always the electrical noise issue with inverters.

Jack,

Doug Talley of Pixel told me that the amp would work with a dedicated 12V power inserter when I contacted him re the improvements of the 1B loop over my 1A. After sending him pictures of my late 1A and it's amp, he determined it to be the then later variant. I guess my question is simple - will my Pro-1A work with a dedicated 12V negative ground power inserter for 'emergency' - or portable - use? I have appropriately sized diecast cases, connectors, etc, and some 1-10 mH rf chokes rated at several hundred mA, too. I should have taken him up at the time on his free offer - at least I'd no. Perhaps, as the designer of the preamp, Jack, you might comment on the suitability of this. If the bias will be way off - and the gain suffers - perhaps we'll look for a 'Plan B'!

John:

The loop amplifier has an on-board 13.8V DC regulator. This has an overhead of 2.2V, typical, 2.7V worst case. If you use the worst case for regulator and overhead plus internal voltage drop in components ahead of the regulator, the MINIMUM DC voltage measured at the output jack on the loop amplifier is 16.8V. As a designer, I have to use the worst case or else risk having some unacceptable level of failure to operate.

If the supply voltage is below this value, correct operation cannot be guaranteed. In the best case with 12V, it will sort of work, but none of the specifications will be met. Maybe that will be OK under some conditions, but the internal voltage regulator will drop out of regulation. The particular regulator used will "try" to maintain the output voltage at 13.8V, but with only 12V on the input, it will obviously fail. When these regulators are operated with lower input voltage than the defined output, they have a 1 to 2V drop, so the loop amp will see 10 or 11V on the internal "regulated" supply rail and as I said all performance data is based on 13.8V, so performance will be degraded.

If you need help in deciding between the Pixel and Wellbrook units, consider this; BNC connectors, a la the Wellbrook unit, are not weather-rated and are most often used with RG-58, even premium examples of which do not have 100% shield. RG-6 Quad Shield and it's connectors have 100% shielding and are more reasonably priced - and weatherproof. It won't matter re the weather-rated nature if you use the antenna inside. Still, incomplete shielding in jumper cables can pick up locally generated QRM. For that matter, the poor internal and case shielding of your very radio, like my Palstar R30A, can pickup QRM!

I would suggest reviewing eham reviews of the antennas (Under 'Antennas: HF Vertical and Wire'.) for more unbiased opinions - as well as mine (JRT3) in the Pixel heading(4 pages) - and Guy's (4NRADIO) in both the Pixel and Wellbrook listings (2 pages). He references his comparison, available from the Wellbrook site, and gives the Pixel it's lowest rating of 3/5, the couple of 4/5 ratings highlighting the need for a rotor. The longer running Wellbrook does have fewer reviewers - and many herald the excellent customer service - but they are all 5/5 (The Pixel gets a 4.8/5!), and apparently doen't need the customer service as much. In all seriousness, they are likely very close in performance - and a poor choice cannot be made.

John

Jack,

Thank you for your reply. You could have chosen a +10V internal rail - and a 10V regulator - but, no....

Yeah, you probably designed the amp with IM requirements - and high linearity, etc. Phooey! As my 12V 14+ A-Hr backup battery runs 12-13.2V, I guess I'll just have to 'try' it and see. It will be for emergency/loss of power, much less common in my newer home, anyway. Probably time to get out my collection of parts destined for my homebrew remote loops... if I could just find my soldering pencils... I did find my 200W iron... moving isn't fun!

Thanks again!

John

In my design (in the group files section) I chose a 12V supply rail as it was best suited for direct operation from 12V batteries, such as Gel Cells, which would take care of any concerns of power supply induced noise. The biasing of the two stages was selected to give a decent power consumption vs. performance. At HF frequencies the NF performance is secondary to IMD performance due to terrestrial and galactic background noise and the presence of numerous high-power broadcast stations.

The performance of my amplifier exceeds that of Pixel and Wellbrook, having a 2.42dB NF at 10MHz. To get better IMD performance than I attained would require a 2W or more power amplifier, which would at least double the power consumption. Using an older transistor such as the 2N3553 or a newer device such as the NE46134 in the output stage and boosting the biasing current to 100mA or so would do it.

Hello Chris,

Running Pixel loops from a Wellbrook ALA1530 Antenna Interface with a 12V dc supply makes little difference unless you are measuring the IOP3 which only changes by a few dBm.

Concerning your last paragragh which you have repeated many times. I am not aware that any one else in the group has been able to get your design working. The NF of Pixel and Wellbrook loops is in the region of 2dB; so I don't see an issue here. Wellbrooks ALA1530S+ Imperium has a much more impressive IOP3 of +55dBm.

Hello John,

Most coaxial connectors are not "weather rated"; they require the user to do this, either by using special tape or in Wellbrook's case using a PVC boot filled with Vaseline; this makes for easy connexion and dis-connexion.

100% shielded cable will have little effect on QRN because of the common mode pick-up with unbalanced cable. If you have an issue with common mode pick-up then the use of common mode chokes and 1:1 isolation transformer at the Rx can help.

Also you need to consider that the system NF is set by the loop antenna amplifier. It highly unlikely that feeder noise pick-up would degrade the antenna, unless this run is very long.

Btw, Guys Atkins a couple years back noticed a noise issue with quad screen cable. We didn't get to the bottom of it, but I surmised that the problem may be to do with the use of dis-similar metals (copper/aluminium) for the screen i.e. any moisture could cause electrolytic reaction resulting in noise voltages.

Kind regards

Andrew

I was wondering how much work has been done and would like to see some discussion on Loop antennas for 75 meter and 160 meter band. I for one have the most trouble with these two bands due things common for most hams. No tall well spaced trees on my property. No huge type antennas, or a way to put up long , very high wires. No huge towers to support any of these either. I would like to reference two web locations that discuss two type of loop antennas that seem to work very well. I plan on making a ground mounted loop antenna for use just for 160 meters and 75 meters made out of 2" aluminum conduit with joints being welded together and a correct size vacuum variable capacitor. see listed links. http://www.bulldogtrust.com/ index12.htm http://www.bulldogtrust.com/index12.htm (3" aluminum tubing 15' transmitting magnetic loop) http://www.standpipe.com/ w2bri/80meter.htm http://www.standpipe.com/w2bri/80meter.htm (80 meter 2" aluminum loop antenna)

Wow, Andrew, a happy customer - and former Pixel, although he didn't identify the model, owner!

You haven't converted me. I see one possible way... I have a similar spot in my walkup tall attic where I could mount your antenna on a five foot mast in a tripod mount, just like my existing Pixel Pro-1A, which would be ~22-25 feet away and whose loop axis would be in parallel. I'll even measure the RG-6 QS I use to insure they are the same length - except for the BNC/F adapters, which I have. I could then A-B the antennas in 'real time' on a mix of receivers, including a Drake R8, Icom R-75, JRC NRD-525, and Lowe HF-150 & 225. Both would be indoors. Unlike Guy's quantitative comparison on an SDR, mine would be a qualitative comparison. All you have to do is send me one of your antennas - gratis. Should it really best my Pixel, I will publish my findings here, as well as my recipe for the crow I would consume in such an event. Let me know if you need my address.

John

Several HAMs are using loop antennas nearly daily (especially Greg N4KGL with AlexLoop) and having great success with them.

See his and other posts on the RaDAR group (Rapid Deployment Amateur Radio):
https://plus.google.com/communities/109283065808971118728

I myself just got an Alpha Loop and getting the hang of tuning a loop antenna. First QSO was from Arkansas to England (UK) with 10W SSB. Not bad I'd say :)

If you are interested, join in on the fun and operate your loop /P or /PM, post to the group and maybe even participate in the upcoming contest http://radar-america.blogspot.com if you like a challenge.

Craig-Not sure what the measurements for the capacitor are, but I know they build them on a CNC milling machine at their shop. The housing that the capacitor is in is buttoned up really well, I mean it has a waterproof seal around the kid and epoxies on the screw heads, etc. Also found out they will be releasing a 100 watt version this summer, as well as a micro-tune version with a 6:1 reducer by May, and eventually they will integrate remote tuning for even a mobile version. I've found they are easy to talk to, but they don't give out any tech data. I think the aluminum strapping is exactly 1/2 inch wide and 1/8 inch thick.
I couldn't find any stock anywhere with those measurements at the 4 major hardware stores. Guess my favorite thing they did with this antenna was make a $249 version available, and if you sign up to receive emails on their site they occasionally
send Free shipping codes out. That's how I got a good deal on mine!

Sent:

Fri, Feb 7, 2014 2:37:50 PM

If you do not mind can you please share some details about the Alpha Loop. I have gathered together some aluminum strapping and other items and would be really interested in things like the width of the strips used for the loop, what size capacitor they use and the size of the loop and coupling loop too. I have a remote tune one I have built that works good but now, (uses aluminum too) but I am wanting to make one out of copper strips connected together. Thanks so much for the information so far on the group. Soon I am going to add my stuff I have done to the group so we can all benefit from my mistake and success. 73's

Correction, a magnetic loop is Not Too Small for these bands, there is no set size for a magnetic loop antenna. Just like any other antenna, the size is governed by what frequency is being used. A loop made from 2 inch aluminum with a length of 80 feet, 24.1 feet in circumference is smaller than a Yagi or quad loop for 160 meters and it is 63% efficient. Not too bad I think.

To small for these bands, but has anyone ever built a loop using one of those spring loaded sun shades for your car as the frame? The sun shades I am talking about are the ones you have to twist into a collapsed figure eight to store. It seems like that would be a very lightweight and compact solution.

I will be purchasing some material from a local ham to build an active receive loop in the near future.

That being said, I also have a KX3. It doesn't get a lot of use; however, I'd like to start this spring taking it to SOTA summits. Here in Alabama, we have *no* SOTA summits above the tree line; therefore, I've been thinking of using wire antennas.

After trying to hear some (not all, but BY, HS, etc.) DX stations after they're posted on the DX cluster and me not being able to hear them, I was put onto a loop antenna.

I also enjoy working QRP.

I was wondering if it would be better to build a homebrew loop antenna and let it pull "double-duty" as a receiving loop and a transmitting loop. Of course, I realize I will lose the preamp if I do that.

Meh, now that I have that written out, I think it would be better to build both.

Thoughts?

73,
Joel - W4JBB

You could use a pair of coaxial relays up on the mast to switch a preamp in and out. Just be sure to short out the preamp input when in the XMT mode.

Some naivete on my part here ... but if the loop antenna is suitable for transmitting, then I'd think it shouldn't need a preamp.

The preamp is helpful when the loop is untuned, and the loss resistance far exceeds the radiation resistance, which make it unsuitable as a transmitting antenna (unless you like doing QRPp). But if you can make a good tuned HF loop with moderately low loss, then skip the preamp.

Sign up for their newsletter at https://amateurradiostore.com/
https://amateurradiostore.com/ to get product updates from Alpha Antenna like those I shared. I also was able to preorder the QRP MicroTune Loop, and of course pre-pay for it. It was $50 more than the standard Alpha Loop. Don't look for the 100 watt version for awhile, perhaps a long while.

Nice read with plenty of info, been reading up on mag loops for quite a while now and never come across that site, thanks for posting the link very interesting indeed, would love to have a loop of that size but think it would create some serious problems with the local anti radio/antenna brigade I have surrounding me so a loft mounted frame antenna loop for 40 and 80 will be the next project, 160 will just have to wait worst luck.

The transmitting loop will have a very sharp resonance when tuned to your frequency. It will act as a good pre-selector. In fact, you can tune your loop by listening for an increase in noise as you turn the cap. If you need more signal on receive, why not just throw out a length of wire? Very cheap, very portable. Only the transmitter needs a good VSWR match to be happy. You would just need a TR switch of some kind. Remember the old adage: 'anything less than a true dipole at least 1/4 wave above ground is going to be a compromise". That being said, an inefficient loop that is portable and easy to deploy is better than no antenna at all! I got a lot of good information about loops here: http://www.nonstopsystems.com/radio/frank_radio_antenna_magloop.htm, Frank is a very avid experimenter and nice guy if you want to contact him with a question.

I don't know man, "specially selected aluminum alloy that has particular chemical properties and physical dimensions" seems a little snake oilish to me (for the price). The most important aspect that effects the efficiency of these antennas is 1. Resistance 2. Resistance 3. Resistance! The junction between the cap and the loop MUST be as low as possible. Some manufacturers apparently weld theirs to minimize R. You may also check out: http://www.nonstopsystems.com/radio/frank_radio_antenna_magloop.htm for a lot of great DIY information on building your own if you are so inclined. I have no idea if the new loop is any better than other loops that have been around for years. There may well be other reasons that make it a superior product. The only way to tell for sure is an honest to goodness "shootout" between competitors. I'm just always a little skeptical of unreferenced claims. The physics of these antennas have not changed since they were first put into service many many decades ago.

Loved your point about resistance, resistance, resistance so much that I called Alpha Antenna to ask them what the correlation between the chemical properties of their specially selected aluminum had to do wth resistance. The answer was so simple, the softer the aluminum the less resistance. They refered me to a sheet on the resistance in different metals. For example the resistance is high when an antenna is made out of stainless steel, because the metal is so dense or hard. Many other metals were listed and of course copper being pliable and a softer metal made it have low resistance as was the case with gold and other softer metals. So basically, Alpha Antenna has chosen a softer form of aluminum based upon chemical properties to lower resistance. Seems there's a lot of information online about this. I hadn't thought of it before, but it just makes sense.

Silver isn't particularly soft and brass isn't that hot in the conductivity stakes.

And we're not discussing pure aluminium, we're talking aluminium alloys.

It's all a negotiation between conductivity, strength, workability, cost of materials, corrosion resistance, frequency (skin effect) etc.

Is the reason that coax is worse than soft aluminum (not rigid aluminum) to build a magnetic loop antenna from because there are thousands of lossy connection points as the braid of the coax weaves itself inside the sheath of the coax? If so, I can understand why a loop with just a few connection points around it would have less resistance than a braid with thousands of connection points. That's the only explanation I can come up with that explains why resistance is less and the skin effect is more on soft aluminum vs braded coax.

I bought a Pixel RF-PRO-1B a couple of months ago and put it up on my roof. I use it with a QS1R software defined radio. I am very happy with it. For me, it works as well as a resonant dipole at any particular frequency, but it does this from below 500 KHz to over 30 MHz. Also, it can be rotated if needed to null out a noise source. If you are only going to have one antenna to monitor the whole HF/MF band, get this.

10485. Measuring very small AC resistances

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-02-13 03:34:16 UTC
From: John Maxwell
Topic: 10485 Message: 10485

I was perusing Chris Trask / N7ZWYChris Trask's paper "A Simple Varactor-Tuned Loop Antenna Matching Network", wherein he makes the sensible statement "...and the designer should always rely to measured data, especially when designing matching networks."

And it occurred to me: I have no idea how to measure _any_ AC resistance (as distinct from impedance), let alone the sub-ohm values he's talking about in that context.

A few minutes work with Google turned up this:

http://www.tnlc.ncsu.edu/files/testing/manuals/ImpedanceMeasurementHandbookRev3.pdf

which looks to be a decent introduction to the subject; I'm digesting it now, but I thought I'd ask if anyone has any advice/pointers/lore on the subject.

So?

Forget about this handbook. What you want to do to
measure a low impedance is to use a TWO port network
analyzer (not a one port NA or an impedance analyzer)
and connect the ports to an SMA tee. Connect your DUT
at the third port of the SMA tee. By measuring S21,
it is possible to work backwards and calculate the
impedance on the 3rd port. This technique works
down to extremely low impedances. In some cases,
you may want to replace the SMA tee with a more
precision fixture that puts the DUT in shunt with
a through line.

Full disclosure: I work for Agilent doing advanced network
analyzer R&D...

until March 14, when I will be retiring.

A 100 foot long receive loop makes no sense. Receive loops
need to be less than 1/3 wavelength at the highest frequency,
which would limit you to 3 MHz. You should probably be looking
at a Pixel or Wellbrook loop, 3 foot diameter. You should
be able to deploy that even in an HOA.

It is fascinating that I would compare any antenna, except in an antenna shoutout, to a loop. I find that fascinating because no where in the design of a small Magnetic Loop Antenna will you find the formula used on the other antenna systems used (i.e. 468/frequency mhz). When an MLA is tuned, for the RECEIVE side there is indeed an increase in the noise floor, a VERY big increase. To say that the receiver does not benefit from a lower SWR is wrong. Also wrong is that the loop is anything but inefficient, rather the efficiency of a loop is higher than other wide band antennas like a dipole. Isn't it true that the effective radiated power is greater from a loop than a traditional dipole?

Harry, I have used an untuned loop about 90 feet circumference (a two turn loop sides 6 metres x 2 metres, hung under the eaves at this QTH.) The plane of the loop North/South used it to listen to the Sydney Hobart Yacht race. Armchair copy, you could almost swell the salt air! Positioning it on the roof may make it susceptable to mains bourne QRN. Could you position it under the eaves of the building. Am not sure what a HOA is. Give it a go, temporarily at first, if it's OK make it permanent. Tuned loops need to be say 1/3 to1/4 wavelength and brought to resonance capacitivly. An untuned loop will have a basic resonance derived from its native inductance and capacitance. Again give it a go. Regards Max VK2TTI

It may be true that HOAs can seem to be overbearing. But everywhere I know of the homeowner is informed of the HOA before buying the home.

That said, one of the great things about a loop antenna is that it can have nearly any shape and can be easily disguised within the normal architectural features of nearly any home. After all, it is just a piece of wire. :)

Harry,

Might you not be better off with an easily homemade multiband dipole, cut and orientated to the frequencies/regions of your preference? Such an antenna is easily hidden, too and its installation may not even contravene your local legislation.

10496. Nested Loop Antenna March QST (duplicate post)

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-02-17 04:28:53 UTC
From: <kb8nty@...>
Topic: 10496 Message: 10496

Just wanted to report, my duplicate (not exact) nested loop post was due to a long delay. Well what seemed long as I posted my first, then the next day I didn't see it up yet, so I created another.
Other yahoo groups my posts usually post within minutes to less than 1/2 hour so I thought maybe I had made an error in the original post.

To my surprise now both appear?...Go figure?...No big deal, just wanted to explain!
So anyway regardless checkout the article, I just wanted to share with the group.

From: Richard (Rick) Karlquist
Topic: 10494 Message: 10497

Yet another worthless QST antenna article.
This is nothing new, it is just the driven element
from a quad antenna. Lightning Bolt sold a 5
band quad 30 years ago. Only they wisely used
fiberglass spreaders, instead of PVC. PVC is a
terrible structural material. They also wisely
used a broadband transformer instead of bandwidth
limiting 75 ohm sections. The article claims
there is no interaction between elements. I
don't know how the author arrived at this, but
I modeled this configuration a few years ago
and found that there is substantial interaction
especially on 10 meters. And I modeled it with
relays at the feed points to open up the unused
loops. As described in QST, it would have even
more interaction.

One of club member built a similar multi-band loop out of fiberglass poles and tie wraps. It performed very well and did many QSLs on field day.

N3FJP & son had built a multiband nested loop...looks interesting...and a good read!

http://www.nxtbook.com/nxtbooks/arrl/qst_201403/index.php

It is featured in the March 2014 QST, and is available also on-line.

N6RK-Rick,
Hello-sure didn't mean to get you upset...sorry if so.
Just with good intentions I wanted to share, some may have been more receptive to it.

Having said that-do know I for one personally value your vast-proven knowledge-especially regarding loops-radials etc,

You and I had been exchanging messages regarding your "remote tuned" loop design. Last communication was this past November. I had expressed great interest in a design favoring 80-40-30 meters, you had referenced a 10' and 20' design, with a few tweaks-eliminations of a few diodes. conversation ended with you stating you were field testing this modified design and was going to check performance of the modified circuit with the 10' loop and also a 20' which would also include 160m!

I had continually expressed my interested, but requested for you work on it only as you could. Very last message you said possibly over that weekend you may give it a field test...My concerns all along were I wanted you to accommodate my request truly at your convenience as I know you remain busy, I was sincere in my interest request, but after November I received no further communication?

I didn't want to harass you or bother you, so I have sat back, checking often for any follow-up reply with your findings. When I seen your reply to my QST nested loop post, I thought it may be an opportunity to touch base once more in the interest and hopes of some positive findings, allowing to move ahead.

Please follow-up if you wish-off list possibly would be best, I am good on QRZ, or at jrl@wowway.com

It was good to see you in there-although sure didn't mean to create a problem with my post. Was just trying to pass on the article to others to view and digest.

Thank you Rick, for working with me on my previous interest in your remotely tuned receiving loop and my inquire we previously had been exchanging communication up till November 2013....Thinking something may had come up, so was relieved to see your recent active post- as now I know all is ok on your end friend.

Kind Regards Rick.

From: <k910dog@...>
Topic: 10471 Message: 10501

If some owns a Alpha Loop antenna can they post some clear pictures of the coupling box and antenna in general. I think these are great antennas for portable use, from descriptions I have heard they are well built but even the manufacture does not have clear pictures of the antenna on their web page. There are hundreds of pictures of the Alex Loop antenna and with this being a the same type of antenna, it would be great to compare the way they are made. I am currently working on a Aluminum loop antenna made from 5/8 inch wide strips of flat bar about 1/8 inch thick. They bolt together and have a permanent bend to them so when assembled form a near perfect 4 foot diameter loop. I am using 1/4 inch Teflon insert lock nuts, washers and bolt to assemble the antenna. Takes a little more time to assemble than the Alex loop but over all I like the way I have it. From the pictures of the Alpha loop, they seem very similar. Don't have any idea what type of capacitor is used in the Alpha loop but at this point it really does not matter. This loop design is always up for improvements. But if anyone has one of the Alpha loop, some clear pictures and descriptions would be great!

10502. air core loop antenna balun

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-02-18 12:26:09 UTC
From: <dj_philonline@...>
Topic: 10502 Message: 10502

Hi, looking for the winding details of a 2.5:1 air core balun for a single band loop antenna, I have read lots of arguments against these but still wish to try one against my 4:1 toroid balun out of interest, there is a guy in the USA selling them with good reviews but for the sake of a plastic tube former and some wire it would not be cost effective to have one shipped to over here in the UK, does anybody on this forum have the winding details or a link to constructing one as I cannot find it anywhere? cheers

M6MRP-Phil,
I have also been following this fellow and his balun.
Seems the reviews are quite positive and yes the balun ratio seems to be more in-line with matching a loop's resonance. Hard to be 100% sure though!
A bit back he posted the actual details and winding diagram, but checking back to help answer your request, I notice he has taken those specifics off his site and eBay, but still includes all the swr plots etc.

I'm thinking I had bookmarked that information...I will try to look and see if it's still there for you.
On a brighter note as an established eBay top rated and power seller, I do know eBay had set up a global shipping program!...This makes the out of US purchasing and shipping much less expensive...However the big issue is the eBay seller needs to sign up to take part in this program, don't know why he wouldn't as it really don't cost the seller all that much more to take part, and it allows exposure to sell world-wide right on eBay.
Take a look on his eBay listings, don't recall his eBay handle, but you can search the item, I think it's called the AG6IF talented balun, and also loop antenna as he sells the balun alone or with the loop antenna wire.
His listing will say if it's set up for eBays global shipping program, if not you can message him-through eBay and request he set it up.

It will sure be less expensive shipping using the global shipping program, than buying and shipping through normal channels.

I'll look to see if I still have his balun design details bookmarked, but may take a few days as I'm in and out of my QTH here recently.

Good Luck Friend!

Thanks Ross, if you still have the details saved that would be a great help, he has nothing on Ebay at the moment I have already checked, I have pondered over this for a while now about using a 4:1 balun which is meant for 200 ohms down to 50 on a loop that is from 125 to 130 ohms or around there depending on how its deployed, it leaves the match way below the required 50 ohms, even a 3:1 would be better but could not find any details on building them? I am in the middle of moving qth at the moment but once settled I intend to try a few experimental windings and see if I can get close myself, about the global shipping on Ebay last year I was looking to purchase a build yourself switchable low pass filter board with all the components from over the pond and the seller told me the USA was not yet signed up for it so shipping was still expensive? if they have now it will make things a whole lot easier as there is so much over there which we do not have in
the UK radio wise and I am desperate for a new battery for my Yaesu FT51r handy which is not available in the UK (the battery) but abundant in the US even in the newer chemical formats but they will not be allowed to be shipped as they are liquid gel.
regards
Phil M6MRP

M6MRP-Phil,
Well having the bookmark indeed saved, when clicking on it though, it brings up the current eBay page, which is not including the diagram.

I am also going to check in my documents files, which would indeed have the diagram, as the document file was not his actual previous eBay page... I will continue to search my document files, possibly I may have cut and pasted the balun design, but many files to search and not sure of what title I would have assigned the file...so maybe just maybe it may be in there, I would let you know if so!

Also researching the eBay global program, it has grown greatly...here are all the countries eBay will ship, at less than direct postal methods, and includes complete tracking!

Australia

Austria

Belgium

Bulgaria

Canada

China

Cyprus

Czech Republic

Denmark

Estonia

Finland

France

Germany

Greece

Hong Kong

Hungary

Indonesia

Ireland

Israel

Italy

Japan

Latvia

Lithuania

Malta

Mexico

Netherlands

New Zealand

Philippines

Poland

Portugal

Romania

Russia

Singapore

South Africa

South Korea

Spain

Sweden

Slovakia

Slovenia

Taiwan

Thailand

United Kingdom

Good luck...PS: Balun designs also offers similar loop balun of interest, yet also not inexpensive.
Continued luck Phil, old boy.

Hi Ross, yes I have seen the balun designs twin toroid 2.5:1 version and I have the winding details to make that one from before they started to market it, never built one yet as I have found the much cheaper 4:1 air core to do the job on another antenna I use so decided that I would try an air core for the 2.5:1 on a loop. That ebay global list has grown quite a bit and the last time I checked, Canada was not in so there is another bonus, I had a feeling the bookmarked link would just go to the newer page as that has happend to me a few times, now I either save the page or harvest the images required, not a problem if you cant find it as I will work it out the old way with trial and error (prob. more error lol)

Well, my bulk buy of BC549C's has arrived, so one more question before I get started on the amplifier...

How closely do I need to match the transistor pairs? Can I just go by HFE reading on my cheap digital multimeter, or for best results do I need to break out something a bit more serious? If so, what exactly? :)

Can I just use my 8405A and check that there's exactly 180 deg phase and equal amplitude on each side?

Thanks,

I never did go to the trouble of determining if hfe imbslance affected the performance, and it's less important for common base amplifiers than it is for common emitter. But, my feeling is that a match of 5% or less would be prudent.

Thanks Chris.

I've just started winding the transformers. I've only got AWG30 wire rather than AWG32 so I've had to use 2873000202 instead of 2873002402 as I an't fit 4 turns of it on the smaller core. Hopefully I can cram it all on the board I'm using.

I still have to sort out some low ESR caps, but I've pretty much got everything I need to build one, finally.

Cheers,

Andy

Go for it! In case you're interested, there's a seller on eBay who is selling the MPS6521 at pretty reasonable prices. I bought two lots of 25 for $10 each from him, which will satisfy my needs. They're basically a 2N2222 with twice the current gain. It's a shame that they were never made in SMT so that they might still be available.

There should be a purple "Upload" button near the upper right corner.

First you need to go into the Files area, then navigate to the directory where you want the upload to appear. Then press Upload.

If you don't see it, then you are probably using a web browser that Yahoo does not support. Ugh.

Attaching a file to an email message doesn't exactly put it into the Files area. It is a different function. It's OK for what it does, but it works differently, and the file does not come up when someone goes into the Files area a year from now, looking for that file. That's one reason why I prefer using the Files area, rather than attached files.

Topic: 457 Message: 10522

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

Doing some quick research on Litz wire and loop antennas, it appears that solid wire is better than stranded and litz wire is the best of all for various technical reasons having to do with electron spin and skin currents.On paper if you use Litz wire the "Q" of the loop should improve and the sensitivity increase. 175/46 type wire seems to be the most recommended size to use. Question is, is the improvement to the loop worth the time and expense to do it and will we snag more DX with the Litz wire loop. Anyone ever done this and have real world comparisons?

10526. Antenna efficiency: Comparing the Alpha Loop & Alex Loop

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-03-02 22:35:59 UTC
From: <aa2nh@...>
Topic: 10526 Message: 10526

Antenna efficiency: Comparing the Alpha Loop & Alex Loop
I have spent much time inputting all of the variables into
http://www.66pacific.com/calculators/small_tx_loop_calc.aspx
http://www.66pacific.com/calculators/small_tx_loop_calc.aspx for the bands that are safe to operate both the Alex and Alpha Loop on, and found why the Alpha Loop has more gain.
The measurements from Alex for his loop are Length of Conductor (antenna "circumference") = 10.3 feet & Diameter of Conductor .32 inches.
Here are the calculated efficencies for the Alex and Alpha Loop antenna's. Please not that the Alpha Loop's measurements are Length of Conductor = 9.92 feet & Diameter of Conductor = .477

Antenna efficiency - The Alpha Loop VS the Alex Loop
From 7 to 7.3 MHz
Alpha Loop; 8% - 9%
Alex Loop; 6% - 7%

From 10.1 to 10.150 MHz
Alpha Loop: 23% - 23%
Alex Loop: 18% - 18%

From 14 to 14.350 MHz
Alpha Loop: 48% - 50%
Alex Loop: 41% - 43%

From 18.068 to 18.168 MHz
Alpha Loop: 69% - 70%
Alex Loop: 63% - 63%

From 21 to 21.450 MHz
Alpha Loop: 79% - 80%
Alex Loop: 74% - 76%

An alarming find when I input Alex's measurements for his loop into
http://www.66pacific.com/calculators/small_tx_loop_calc.aspx
http://www.66pacific.com/calculators/small_tx_loop_calc.aspx for 10 through 12 Meters occurred. On those frequencies a RED message appears that says:
"To avoid self-resonance, the conductor length for a small transmitting loop antenna should be less than 1/4 wavelength."
I now understand why the AlexLoop should not be used on 10 & 12 Meters, which is because exponential increases in resistance will occur on a small transmitting loop when self-resonance occurs, which can damage equipment.
For more information on this, see the section titled "Inductance and self-resonance" here:

10531. N6RK Remote Tuned Loop Experience

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-03-14 01:59:09 UTC
From: <kb8nty@...>
Topic: 10531 Message: 10531

To the group;

I am planing to purchase a receive loop antenna tuning network from N6RK Rick.
Certainly not to question him or his talents.
Already having a shielded coaxial loop, this would be the antenna tuning network, and the remote tuning box to assemble and connect to my loop.
Of course this is a well received proven type of receiving antenna published in the NCJ magazine some years ago.

I was just curious has anyone either purchased or built this exact system?
If so wondering how it may have worked out for you, or did it?

Respectfully I am not interested in the different types of receiving antennas. EWE's K9AY, beverage ETC. ETC.that you may have found to be better.

I am more so very interested in your experiences and opinion of this specific remote-tuned loop.
How has it performed, did it, how did you mount it, how high, how close to your transmit antenna,use a rotor ETC.?

By means of severe space restriction, it is this type of receiving antenna I am selecting, and have specific only interest in and wanted to learn from anyone who may have any actual experience with.

Thank you very much in advance for any potential replies, advise and help.

From: <k910dog@...>
Topic: 10534 Message: 10534

I was hoping for some detailed discussion on the best/ideal location of the tuning capacitor, (motor if remotely tuned) and coupling loop/RF feed method. All pose design problems and considerations weather it is permanent mounting or use or portable and supply's needed or on hand. But if all these things aside , what would be the best RF configuration of the loop. Most portable loops have the tuning capacitor at the bottom for obvious reasons and the RF feed point at the opposite side (Top) of the loop. What comes to mind is the coax crosses the RF path to the transceiver. If you reverse this and place the tuning at the top this makes it more difficult to tune the antenna and also makes it more difficult to keep from interfering with the loop while tuning. Now if you consider the point of the tuning capacitor has the most RF this removes it from the operator and possibly helps with the signal/RF being at a higher point. If you use remote tuning in this configuration, this removes the interference from the equation but possible RF problems being so close to the motor-and this too may cause interference. In theory, and I am just guessing, you could put just the capacitor at the top, RF feed at the bottom and maybe use some kind of non conducting shaft from the capacitor down to below the loop, away from the RF field to a motor, this seems to me an ideal set up. This of course is not good for portable but maybe just design ideal. Please i know there are a lot of experience persons that have tried or maybe tested some of these different configuration, we would all benefit from the knowledge. Thank you

There is a third approach to the design of a remotely tuned transmitting loop antenna that does away with the expensive vacuum variable capacitor and the coupling loop:

http://www.home.earthlink.net/~christrask/Paper012.html

I'm presently looking at a variation that requires a single variable capacitor instead of the ganged dual.

I am currently gathering all the parts to make a remote tuned 15-40 meter loop antenna similar to an Alpha loop except the design will have some improvements for my use and tastes. This will be for portable use but not necessary "portable as in an Alex loop or Alpha loop antenna system. Mine will be made out of common found aluminum strips, small inductance loop at top, tuning capacitor at bottom connected by non-conductive shaft to DC motor/reduction gear. I will connect the tuning capacitor by 1/4 non-conducting shaft to DC motor/reduction gear well below the elevated loop using 1/4 universal couplings and 1/4 nylon bearing flange mounted. This will allow there to be free movement in the shaft and make it easier to mount with less stress on the whole system. This also allows the dc motor to be removed away from the RF field of the loop. This will take more time to set up, weigh more and be less portable due to components and size of space needed to pack. It will also be a lot more users friendly and easier to operate, change bands and get more precise tuning due to no proximity effect of manual tuning. I do mostly portable HF, without the worry of equipment needed, like field day. For strictly fast set up and portable HF, I do not believe there is much improvement that could be made to the Alpha loop or the Alex loop for what they are intended for use. When complete I will post pictures and step by step details. My main problem with current loops is they are the design for portable, quick set up and light weight. With these design requirements in mind it limits there construction. These same thoughts have me planning two big loops I want to build for permanent use for 160 and 75 meters. I will never have the real estate or the towers, tall trees to put up a proper large wire loop or wire antenna for those bands and from several articles I have read, a proper single band loop with vacuum variable capacitor makes a great antenna for these bands.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1. * Justice AM Loop Antenna (Active)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Long LoopStick Antenna for MW DXing
Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

10539. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-04-01 12:29:03 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 10539

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

10540. Re: N6RK Remote Tuned Loop Experience

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-04-02 01:45:51 UTC
From: <summersb@...>
Topic: 10531 Message: 10540

Hi Ross:

I built a copy of N6RK's remotely tuned loop and experienced little success. I was able to null a particular noise source in one direction but still had a very high noise level. To put it another way there was little improvement in received S/N ratios. I would also add that over the years I've had little success with any type of shielded loop. I've come to a couple of conclusions. 1) living in suburbia noise is coming from all directions and there is no single source to null out, and 2), this following an email exchange with N6RK himself as well as other readings, there is a very high probability that noise is re-radiating from my 56ft high tower and the loop being only 60ft or so away is unable to do its job. Solution is to detune the tower which hopefully I'll get around to this summer.

The base of the loop is about 6ft above ground and is turned by a TV antenna type rotator.

As always, YMMV.

Brian,
I was so pleasantly pleased to see your reply, not so with your results yet none the less what a pleasure to finally receive "any" response related to my specific inquire...for that sincere appreciation!

Well here in a small city lot with it's share of overhead power, cable, telephone lines I am seeking to improve my lower band receiving situation. Running a Mosley TA-33M WARC up on the rooftop and a Butternut HR9V ground mounted vertical w/ 125 radials,
I get out...sometimes use the yagi to receive with on 30-40-80 meters, but looking for better.

I did build a shielded coaxial loop 20' at 5' per side, notched at top and all one piece of RG-6. The feed line runs directly into shack. Issue is I built no tuning network into it...A surprise to see it does work to a degree, it does reduce the S/N but lacking any tuning abilities.
Its on a 3 foot tripod on ground w/rotor and about 40 feet from vertical.

I have read great reviews and have had conversation with N6RK, and was going to purchase an assembled unit as now being disabled I am unable to build and was asking for help with any users experiences.

Possibly you may benefit with the detuning of the transmit antenna, this is not so uncommon, but discouraged with reading your results.
I am thinking something don't sound as it should, I know there are better receiving antenna choices, yet I do not have the room, and even with my poorly constructed loop without any tuning, it did offer some help!

I wish to thank you sincerely for taking your time for your reply...If you get the chance do try the detuning process, I think your loop should do better than you experienced!

I'll post my follow-up experience for what its worth when I put his loop into play here ...Thanks again friend...I wish you luck with your loop there.

My pleasure Ross and I wish you well in your efforts. My goal has always been to improve reception capability on 160 and I'll have another go between now and fall. The tower which has a big beam on top is shunt fed for 160m and radiates well. Approx 3,000 feet of wire buried in the back and front yards.I can often hear people calling me but can't pull 'em out of the noise. It's tough!

VE7JKZ - Brian,
Frustrating it is to know someone is calling you and you cannot pull them apart from the noise!

I have experienced that at times when putting out a CQ, I will hear them in there calling but "in the noise"
It does make you feel uneasy, then I wonder how are they hearing me is it propagation, or their receive set-up being better?

Here also dealing with a city lot, the noise varies. It's time for me to get more set up with receiving on the lower bands here. I have done my operating up till now with the HF9V Butternut w/125 radials and Mosley TA-33M-WARC.

My big issue is space limitations here, so focusing on the loops. I did try a BOG but it seemed to pick up a lot of noise from my extensive ground radial field.

I have learned to appreciate the study and theory of SNR and know that's what I have to hone in while balancing the selectivity & sensitivity working with the loop here.

So curious with your poor experiences with the loops, possibly some common mode chokes on your loops feed lines may help, because if your getting noise on them all, it may help experimenting with such, in the effort to decouple the noise from traveling in on your feed line.

Wishing you luck...I will report on my N6RK loop findings when I can here in the future.

Thanks again for your input...

Signing off.

Loop antennas should be about the best you can do on receiving. That is why they were employed by the military during the world wars. That is not to say that they are not in need of careful tuning. I cannot remember a comparison of technologies where the loop wasn't the winner. Perhaps I am naive in that respect but if I recall correctly loop antennas are capable of receiving nearly twice the signal of other designs.

I still would like some input on angle of take off of a magnetic loop comparing the capacitor at the top or bottom along with any other information on best placement vs where they placed for function. Most loops are anywhere from 3.5 to 10 feet above ground when used in vertical position, with this in mind where should the capacitor be for the best use of this antenna. I have included a drawing of my antenna i am currently building and testing and now I am thinking of placing the capacitor at the top with a long non conducting shaft running through the diameter of the loop to below it. This will remove coax, DC cable, motor and gear box away from the RF field of the loop.

You can find my paper on shielded loops in the group files sectio by the name of:

"Shielded Loop Aerials Rev 0.pdf".

And a suitable wideband amplifier is on my web page at:

http://www.home.earthlink.net/~christrask/Paper009.html

Hi Chris. For sure it's a very good preamp but it implies too much coils for me. I have some toroid but can't identify them. Unless you have one readily made for sale. I forgot to mention that my band of interest is AM broadcast and LW. So, a preamp working from 100kHz to 2mHz is all I need. There is no longer AM station in my town. Overload is not an issue.
Thanks

I recently read of one claim for greatly improved performance of a shieled loop when changing from RG59 to 3/4" hardline for the loop....same diameter. The conclusion was that the much larger center conductor of the hardline was the reason. Is there any other evidence that might support this?

When I did my in-depth work on loop antennas, I found that as the diameter of the element (NOT the loop diameter) was increased, the efficiency improved. This was a result of the larger cross sectional area of the skin surface of the element, which results in lower bulk losses. The same result can be extrapolated to show that a larger diamer inner element of a shielded loop will have lower bulk losses, therefore better efficiency.

would it be something one could notice (measure) on a 10' loop? My present 10' shielded loop uses RG-58 and going to RG-8 or RG-11 would really increase the weight. Is it something worth considering? How would the increased efficiency manifest itself...increased overall system gain...better S/N ratio or ...??

I sent you a couple of files to illustrate how the loop element diameter and frequency affects the efficiency of a non-shielded loop antenna. The results can be extrapolated to understand the effects of using different diameter materials for a shielded loop.

Something that I've been meaning to look into is the overall effrects of the characteristic impedance of the shielded loop element. We often use a small diameter wire for the inner element and sometimes even use 50-ohm coax. But, the terminal impedance of the shielded loop is small, commonly less than 5 ohms. That being the case, the characteristic impedance of the shielded loop element should be the same as the terminal impedance. But, this would be a bit difficult to construct, possibly using 1/2" tubing for the outer element, 5/15" tubing for the inner element, and some plastic tubing for the insulator. Not sure of the benefit of doing this would be worth the effort.

Thanks for the articles Chris.

My present 10' shielded loop is used only for the BCB and below so much of this would likely not affect my system as much as if it were to be used on higher frequencies,

yes...I agree. I believe Everett constructed a similar high efficiency shielded element but not sure if he was able to compare it with RG8 or RG11 at low frequencies to measure the changes. In a system limited by atmospheric noise levels I'm not sure there is much to be gained by rebuilding my present RG58 shield element. At 10' diameter, anything heavier would eventually suffer storm failure here on the ocean.

There may be an indirect advantage. With the bulk resistance reduced, the Q of a series-tuned loop would increase, which would result in a narrower tuned bandwidth and consequently lower received noise power.

PVC wouldn't be good for Q. An HDPE jacket would be far superior.

Maybe there's irrigation pipe available with suitable diameters?

Guys,

One of the best things that I have found is PAP pipe (polyethylene - aluminum-polyethylene). I found some 1" on eBay and have used it to build both a 1 meter loop and a 6' diameter shielded loop. By using number 22 magnet wire as the inner conductor, the capacitance was about 7 pF per ft. I have the 6' loop configured in a möbius. It is the best working antenna I have covering from daylight to 33 MHz. It problem will work well above 33 MHz, I just don't have a receiver to listen above that. I plan on building a 7.5 ft loop using 1.5" OD 0.30" aluminum tubing in the next 2 months or so.

The PAP is used primarily in Europe for Gas line feeds and in floor heating. It is very easy to bend.

Guys:

Wondering what the "advantages / disadvantages" are for a Shielded Loop vs a non-Shielded Loop for the same Loop DIAMETER. I have a "feeling" that one has a better "Q" than the other - implying one has better "UNWANTED" signal rejection.

Some of the advantages are low frequency noise immunity and isolation from nearby objects. I have a section on the noise immunity on my paper on shielded loops in the group files section.

Garey Wittich Santa Monica,CA”

Garey,

A balanced 1 turn loop of the some diameter driving into a low z input amplifier will have similar near E field rejection as a screened loop. I did a lot a work with screen and unscreened versions of the ALA1530 in 1997 and to be honest I didn’t see any advantage with shielding. Having to use a smaller diam. conductor increases the loss compared to using a conductor of the same diam. as the screen.

Notwithstanding the above, a screen may be necessary for a tuned or multi-turn loop if it can’t be balanced.

A loop antenna primarily responds to the magnetic component of a radio wave. An unshielded loop will also pick up some of the electrical component, and not necessarily in a symmetrical manner. If you want the deepest possible nulls and a symmetrical pattern, either for direction finding or to null out an unwanted signal, a shielded loop is better. Also more immune to local noise.

Hi all, I'm experimenting with various remotely tuned open air loops and ferrite loopsticks. I have made a remotely tuned varicap diode assembly and a remotely tuned variable capacitor assembly (using a stepping motor w/arduino). I intend to experiment with each on my 4x4 open air box loop and soon a loopstick as well. I am also building up a differential preamp so I will not have to bother with a second pick up loop. My question is: What is the disadvantage of using varicaps (in pairs) compared with using a variable capacitor to tune a loop? Do varicaps have any tendency to overload or buckle under strong noise conditions? Put another way, Does the mechanical complexity of a remotely tuned variable capacitor provide any advantages over varicap diodes with all other things being equal? According to circuits I have obtained on the net, I can drive a differential preamp with either setup. A thorough search of the net has not provided me any data concerning my question. My only conclusion to date is that my stepping motor imparts significant noise into the antenna when it is operating. This is not actually a bad thing in that it tends to serve as a tuning aid when using a traditional receiver. Of course when using an SDR with a spectrum scope, the noise is a distraction because one can see the antenna peak moving along the frequency domain as it is tuned. Any thoughts welcome!

Varicaps can produce serious IMD products when used for remote antenna tuning, especially in the presence of strong nearby broadcast stations. Variable capacitors will always give far better performance in those circumstances. Varicaps will also degrade the equivalent antenna noise temperature due to finite bulk resistance, whereas variable capacitors have little if any series resistance.

I have not gone to the trouble of doing a comparison between the two, I just know from experience about the IMD problems of varicaps. I have recently devised a single variable capacitor approach to tuning a loop antenna, and if I can ever get my act in gear I'll publish it online as I have done with other designs.

Varicaps definitely can rectify and create QRM from strong
signals, be they AM BCB stations or nearby ham stations
or if you are running SO2R. The back to back configuration
helps but you can still have rectification.

You said you were using a preamp. Preamps also create
their own intermod so it can be hard to determine whether
any given intermod is due to the preamp or varicaps.
This includes built in preamps in radios. The IC706
preamp is bad for this.

Wow answers from the living legends themselves! I have a few of your documents in my files that I have been educating myself from! The balanced (differential) preamp I am gathering parts for is from a paper by Lyle Koehler. It seems to be a variation on a common design as it appears to be used by at least two of the three builders of commercial loopstick antennas. I am guessing the balanced, center tapped loop design allows the loop (or interchangeable coils) to be grounded thereby protecting the FETs from ESD. Anyway thanks for the great feedback. I was guessing that the varicaps had some sort of Achilles heel that keeps the antenna builders looking for good old fashioned variable caps. My remote variable capacitor design is nothing earth shattering but I have made it to use standard cat5 cable and cheap eBay stepper motors from China. I use the three left over cat5 wires for positional feedback from a pot attached to the cap. All 8 wires get used and cat5 cables are everywhere so no custom cables need to be built.

Is that the one with the balanced MPF102 input stage and a balanced 2N2907 output stage? I have reservations about that approach as the low impedance of a loop pretty much dictates a low input impedance amplifier with series tuning. His design is more appropriate for use with a short dipole, which can be a pretty good small antenna. But, his amplifier is fairly simple.

Yes, that's the circuit. http://www.lowfer.us/k0lr/bal-pre/bal-pre.htm http://www.lowfer.us/k0lr/bal-pre/bal-pre.htm. I thought the point was to have such a high impedance that the loop/inductor was not effected by the directly attached preamp. Another interesting design is from the late Ralph Burhans. I bought and used his preamp way back in the 80's and lost it. I was happy to find the design again. However, it is not a tuned design and I'm not quite sure if I can just slap a tank circuit on the transformer input. http://members.shaw.ca/ve7sl/burhans.html http://members.shaw.ca/ve7sl/burhans.html

I'll look at that later when I have a WiFi connection. The loop antenna is best viewd as being a current source with a series inductance and a low series resistance. When seen that way, series tuning with a low input impedance amplifier becomes obvious.

I think I placed a 1- or 2-page PDF files in the group files section that showed schematics for simple active antenna amplifiers using the CA3046 transistor array. If not, I'll look around the see where I put it. It's not on my office computer, so it must be on the laptop.

I've been using varactors for MW and LW loops for years. There are a couple of things to be careful of.

When using a back to back configuration I've found it best to match them as closely as possible. An imbalance increases the chances of IMD and other problems.

The lower the signal level across the varactors the better. I use set of 4 pairs (8 total) MVAM109s to tune a ferrite loop and have used as many as 10 pairs (20 total) for a LW air core. The higher capacitance allows for fewer windings and lower AC voltage across the junctions and matching is easier if 4 parallel varactors are matched to 4 others. I got lucky and bought 300 of them for next to nothing, rejected lot with 50 of them being defective but I still see those or similar in bulk on Ebay from time to time.

I also use a second center tapped pickup loop with a balanced MOSFET preamp feeding a balanced line to the receiver. Even with 3 BC stations close enough to hear on the toaster I don't get any noticeable intermod.

I prefer varactors mostly because I stick to the KISS principle as much as possible. A well regulated reference voltage, a 10 turn pot, a single op-amp, a few resistors and caps and one wire is all that's needed for control.

I've heard of people having problems with varying ambient conditions. The attic above the garage where the loop was mounted goes from -30F in winter to over 140F in the summer. The antenna is "noisier" the hotter it gets but I can say the same for any MW antenna since atmospheric noise in this region is very high from April to October so it may be junction noise or it may just be background/thunderstorms. Probably a combination.

One other problem with varactors is testing. The loop design
I published in the National Contest Journal cannot be tested
with the MFJ-259 impedance meter (and probably similar units)
because the drive level is too high. I only recently discovered
this. I did all the development work originally with an
HP 4815 vector impedance meter. I also found that if I
used an Agilent E5071C VNA, I had to reduce the drive level
below the default level of the instrument.

When I measured the batch I got I built a buffered VCO with the L.O. coil from an old MW radio using a socket for the varactors to test the frequency output at 12 discrete voltages using a 12 position switch and resistors.

Fed the output to my scope and the output from the scope to a cheap frequency counter. A bit of Math (and a spreadsheet) gave me the cap. values at different voltages and monitoring the waveform on the scope showed if they were noisy or unstable. Neither the scope or the counter had to be NBS traceable or anything since I was comparing apples to apples so to speak and in circuit stray capacitance would be more than the measurement error anyway.

Still have the test jig around here somewhere....

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)

Long LoopStick Antenna for MW DXing
Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

10582. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-05-01 11:46:52 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 10582

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

>where I put it. It's not on my office computer, so it must be on the laptop.
>

I found that file in the group files section. The title is:

Active Antenna Amplifiers for Low Voltage Operation RevA.pdf

Although the designs are for low-voltage operation, they can be used for supply voltages up to 12V. For practical purposes, the schematic on the second page is probably the most suitable, and the one on the third page is for demanding situations where even-order distortion from strong signals is a serious problem.

From: <3ym3ym@...>
Topic: 10570 Message: 10584

This may be interesting for LW and VLF/ELF work. I suspect that above 1MHz other effects and non-idealities swamp the common mode rejection ratio of the amplifier.

10585. MFJ-1788 housing needs painting

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-05-05 11:32:51 UTC
From: Alan Sutherland
Topic: 10585 Message: 10585

Hi All:

Before moving to an apartment with balcony, where the MFJ loop will stick out like a sore thumb, I need to paint its black ABS housing white or another light color.
MFJ advise us not to use a paint containing metal.
I have researched and found that nearly all exterior paints, in Europe at least, where I live, contain titanium dioxide or zinc oxide.
Is the concentration of TiO2 so small and dispersion so great that it does not affect tuning of the loop?
Does anyone have experience of painting this housing?
Please share your experience or ideas with me and others.

Thanks for the taping idea for the black housing of the loop. That would probably be the last resort! The loop will be exposed on the balcony in this continental climate; the tape would probably become messy and short lived. But maybe worth a try.
Some people have successfully painted the housing.

I think when they said "metal" the meant the elemental form
of the metal, not a compound like TiO. In any event, I
would not worry about the effect of paint, because it will
be negligible compared to ABS pipe, which is a low quality
dielectric.

From: Frans.Vink@...
Topic: 10585 Message: 10591

As a chemist I would agree, metal oxides etc. do not inherit ANY metal free electron behaviour and would therefore not have a negative effect. I would expect they mean 'Metallic' paint, that actually contains small metal particles to give the shiny appeal.

Hope this helps,

Frans

Hi Frans, Rick and all who responded:

This is very reassuring and I will probably use an exterior wall paint of matching color.
That is what IZ0FYS has done in Italy. His QRZ.com page shows photos.

Frans, if I use a primer spray with <50% acetone, do you think it would soften the ABS plastic?
The black cover is a supporting part of the structure and I would not want to weaken it.

The acetone in paint or primer evaporates very quickly and so has little chance to permeate the substrate. I did a search for ABS and Acetone and found some interesting info on using a heated acetone vapor to smooth ABS printed parts where they left the parts in the vapors for an hour or more. From what I saw I think you will be very safe with the paint.

10597. Best ferrite matierial for tropical band?

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-05-30 12:55:46 UTC
From: n3ikq@...
Topic: 10597 Message: 10597

I've built a stand alone LF and bcb loopstick antenna (basically a Palstar LA30 clone) using type 33 and 61 ferrite rods for LF and BCB. So far so good, it works great. To finish up the project I'd like to build a tropical band plug in as well. What would be the best type 7.5 inch ferrite rod and Litz for higher frequencies into the tropical bands? I'm thinking that type 61 would work but there is a type 43 on eBay right now supposedly good for >2Mhz. Thanks for any advice.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Long LoopStick Antenna for MW DXing
Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

10599. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-06-01 12:09:22 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 10599

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Hello,

I'm planning to experiment with a small loop (circular shape, 1 meter dia) passively connected to the 50R feed line. It'd be used for reception in LF and MF bands.

I was checking the web and found diagrams and notes recommending step up transformer ranging from 1:10 to 1:100.

Would you recall any references discussing this type of loop and the needed step up xmfr?

All tips and suggestions are welcome!

Thank you,

I don't have references handy. But I think the reason for the step-up transformer, is because the small loop has an exceedingly low radiation resistance, and one gets better power transfer with the step-up XFMR. You get the most power transfer from antenna to receiver when you have a conjugate impedance match, and the step-up comes closer to matching the real component. If there is also a tuning capacitor in there, that might also help, but maybe not necessary for an RX-only antenna.

On LF and MF, maximum power transfer (a perfect match) is not needed because background noise tends to dominate. (i.e., more signal from the antenna does not give you more S/N.) But if the mismatch is too great, the received signal may be so low that the S/N suffers. So the XFMR helps with that.

That'd be my guess.

Regards,
Andy

Hi Max. It'd be a single turn, 1 meter diameter or a bit more, untuned. The loop terminal would be connected to a step up xmfr.

G'day again, I would suggest that you construct a temporary transformer using a split ferrite clip on device. Used to clamp on cables for interference reduction. It is much easier to wind different ratios on a split ferrite than on a toroid type. However, I think you might be disappointed with the results from a single turn loop. Give it a go by all means. Regards again Max vk2tti.

Hi. I have a wellbrook ala100. La (large aperture) loop antenna. I purchased this about 3 or 4 years ago and I'm finally getting around to really using it. My question is can I feed it with 300 ohm twin lead??. I have two rolls of this lead in and I would like to put it to good use instead of purchasing coax. Thankyou. John

Hello John,

Under no circumstances use 300 Ohm twin lead.

There are 3 issues to consider:

A reverse polarity on the feeder would damage the head Amp.

If you get it to work, there may be instability.

The feeder will be un-balanced and pick up local noise.

Kind regards

Andrew

Thanks Andy!! You're right I forgot all about the voltage feed. Glad I asked. While I have your ear. I have an older wellbrook " - center" power supply and I have a newer + center power unit. Is it true that I can use either of these with the antenna unit as long as I have the polaritys correct on the power unit I.e. - center walkway with negative center power unit. + center power unit with positive center power unit

John,

The polarity of the Interface and power supply must be the same. If you get it wrong the series diode on the older interface (-ve inner) will protect the loop from a reverse voltage. The newer (+ve inner) has a protection diode that will pull the resettable fuse.

Kind regards

Andrew

Thanks Andy!! You're right I forgot all about the voltage feed. Glad I asked. While I have your ear. I have an older wellbrook " - center" power supply and I have a newer + center power unit. Is it true that I can use either of these with the antenna unit as long as I have the polaritys correct on the power unit I.e. - center walkway with negative center power unit. + center power unit with positive center power unit

Hi. I have a wellbrook ala100. La (large aperture) loop antenna. I purchased this about 3 or 4 years ago and I'm finally getting around to really using it. My question is can I feed it with 300 ohm twin lead??. I have two rolls of this lead in and I would like to put it to good use instead of purchasing coax. Thankyou. John

Hi Andy understood, but the actual active antenna portion or the "active antenna head" doesn't matter if it's getting the older -ve center voltage setup or the newer +ve center voltage setup. Is that correct?

John,

The active portion is in the Head Amp., so it doesn’t matter which interface you use. The exception to this is with the ALA1530S+ and the ALA330S which have a 2 transformer Balanced Norton amplifier (2 x 2N4401) in the Interface to provide an extra 9dB gain with a +55dBm OIP3.

Btw, it was one of Chris Trask’s papers that suggested the 2N4401 for exceptional linear applications! However, the On semiconductor manufacture appears to be the best. Unfortunately the complement On Semi 2N4403 (T092) is now obsolete.

Kind regards

Andrew

Thanks again Andrew. Yes i'm dealing with the ala 100 large aperture, but its good to know re the ALA 1530 and 330 as i suspect they use the same interface as the ALA 100 series. Great antenna BTW.

Its been awhile, but im finally starting to get around to some DXing with it, especially on the NDB and BCB bands. Are you still looking for pictures of loop installations?? I can send you one of my modest loop if you like.

Also, Is the receiver one is to use with their ALA 100 transformer isolated or capacitive isolated from the DC in the interface unit??

Thanks again john

Hello all;

Name is Joe and this be my first post here.

The question of whether to use tuning diodes or a mechanical cap is extremely interesting, and I think that many of the concerns ment here are valid. I also think that there is another consideration, and that is "What is your expectation for the Q of your resonant loop in the design frequency range?" One has to consider which tuning means would have appropriate Q for the desired frequency band, and you might have to answer questions such as "Which approach will give me higher Q", if Q is what you are after.

My current workhorse resonant receiving loop tunes between 2500 and 7800 kHz, and is used primarily for tropical band and SW pirate DXing. This is a four turn loop built on a square PVC frame which gives a 20" side length. The winding is 10AWG type TEW untinned; a 3" center gap (the length of a standard PVC cross) is maintained between turns 2 an 3 to depress parasitic capacitance. This is tuned by a pair of BTB NTE618s or MVAM115s, and buffered by a balanced JFET (MPF102 and U310 pairs) cascode amp. Amplifier Vdd, tuning voltage, and RF are multiplexed on one 180 foot continuous run of F6 coax between the amplifier/tuner head on the mast and the power supply/signal splitter in the shack. The loop is mounted on a light duty rotator which is primarily used for depressing local QRN.

Using the BTB tuning diodes in this tuning scheme gives me a fair-weather loaded Q of between 200 and 250 over the mentioned frequency range. Using the highest quality mechanical variable caps I own (I have not tried vacuum caps yet), the best Q I have observed is less than half of the Q exhibited by the diodes in the lower SW frequencies.

BTW, I do agree that a diode tuned resonant loop may favor colder weather; on the two mornings here in Chicago where the temp bottomed at -17F, I was able to measure a loaded Q of approximately 330 on this loop. I have yet to bang through the numbers to find the most likely cause (or whether the measurements were bogus!). In the hotter weather, it's harder to tell (and possibly moot) given the generally higher summertime noise levels in these bands.

---In loopantennas@yahoogroups.com, <n3ikq@...> wrote :

Hi all, I'm experimenting with various remotely tuned open air loops and ferrite loopsticks. I have made a remotely tuned varicap diode assembly and a remotely tuned variable capacitor assembly (using a stepping motor w/arduino). I intend to experiment with each on my 4x4 open air box loop and soon a loopstick as well. I am also building up a differential preamp so I will not have to bother with a second pick up loop. My question is: What is the disadvantage of using varicaps (in pairs) compared with using a variable capacitor to tune a loop? Do varicaps have any tendency to overload or buckle under strong noise conditions? Put another way, Does the mechanical complexity of a remotely tuned variable capacitor provide any advantages over varicap diodes with all other things being equal? According to circuits I have obtained on the net, I can drive a differential preamp with either setup. A thorough search of the net has not provided me any data concerning my question. My only conclusion to date is that my stepping motor imparts significant noise

into the antenna when it is operating. This is not actually a bad thing in that it tends to serve as a tuning aid when using a traditional receiver. Of course when using an SDR with a spectrum scope, the noise is a distraction because one can see the antenna peak moving along the frequency domain as it is tuned. Any thoughts welcome!

Hi Everyone,

I just completed a project where I needed to wind a ferrite antenna. Way too much to do good by hand. This winding machine was invented to do the job. The completed working model is on my pages at this link. It uses an Arduino UNO board, code, and common items you can obtain easy. This can run unattended for hours to do big core ferrite antennas that has a lot of wire to be wound. This one wound 24 miles of wire for me with little attention except to change wire spools..

Hi Dave,

These were special for one purpose only narrow band antennas. L=1114.6 H and 1148.8 H for the two of them.
It took about 260 NF capacitance to bring them on frequency at 7.8 Hz.. Each trimmed individually. The self resonance is very low I think in the 100-200 Hz area. These are in use at less than 1 Hz bandwidth for detection.

Hi Joe, thanks for the post. I'm quickly amassing a small army of loops so I can learn for myself all of the good advice I've been getting. The first little tidbit of reality comes from comparing my recently homebuilt loopstick (Palomar clone) with my newly acquired Quantum loopstick from eBay. I needed a "standard" by which to compare my home built attempts. So far, my homebuilt model compares very favorably with the commercial version. I need to quiet things down electrically by getting some matched JFETs and paying attention to critical component values to keep the balanced amp really balanced. If I substitute a regen type preamp circuit I can improve the Q as well. My plans for the loopsticks are to build a remotely tuned outdoor model and possibly springing for a monster ferrite rod from Stormwise to replace the current Amidon 7.5" rod. I've become a big fan of remote tuning as I've been playing with stepping motors for the past year or two and I've built a few that use simple cat5 wire making hookup easy.

The big surprise is how much better even my 30" passive air loop performs against the loopsticks. Of course I was aware of this but there nothing like actually observing it myself! My next steps are to compare tuning the loop with varicaps vs the air variable cap and to try getting the best inductive match to my 50 ohm feed line. Additionally I want try connecting a balanced preamp directly to the resonate loop and observe the performance of that arrangement vs the passive coupling approach. Another few months and dollars later I'll finally be up to speed on what everyone else already knows! Well at least I'm having fun doing it!

Dominique,

Eigenbau is german and it means DIY or homemade.

The description is limited, but I think it is a tuned loop with three windings. Diameter is only 50 cms. Because a power cable (230V) is mentioned it will probably be an passive antenna with a remote motor drive for the tuning capacitor. In Germany there is a supplier of more or less identical antennas, I just can't remember the name. The small loop is a pick-up loop I guess.

The mechanics at the bottom of the loop housing could also be of a rotator.

The two large wooden loop structures are also very interesting.

It's a 3-turn loop with inductive coupling. Interesting design as I've never seen this form of coupling used with multi-turn loops.

10645. Shielded Resonant HF Loop

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-06-23 21:22:05 UTC
From: jfarley44@...
Topic: 10645 Message: 10645

A while back some insulators on a nearby power pole went crusty, and began to spew horrendous RFI around the neighborhood. I prefer to DX with an unshielded resonant loop, and even with azimuthal "nulling" my noise floor here was way too high - about an S7 - for my liking. After several calls to the Power Company over several weeks, I went into Repair Despair. The backup AL1530 worked OK, but I knew that I was missing DX.

I decided to see if I could get the best of both worlds, that is, a shielded resonant loop. I built a prototype of the loop using one of my standard loops on a PVC frame, some foamboard, aluminum foil, and tons of Scotch tape. Here's a pic:

http://i1049.photobucket.com/albums/s387/jFarley44/LunarLander_zps4593ae91.jpg
http://i1049.photobucket.com/albums/s387/jFarley44/LunarLander_zps4593ae91.jpg

The idea was to enclose the resonant loop inside a cobbled up shield (maintaining a 3 to 4 inch gap between the windings and the shield) to see if that would help to suppress noise pickup. The idea apparently has some merit, and here is a sample of audio capture which directly compares the audio capped with the unshielded standard RL to that capped with the shielded RL

http://www.mediafire.com/listen/4rdk48824h6tnqd/CFRX_6070AM19Oct12_2030z.mp3
http://www.mediafire.com/listen/4rdk48824h6tnqd/CFRX_6070AM19Oct12_2030z.mp3

The first 42 seconds of the audio is from the unshielded RL, and the balance is via the shielded RL.

Shortly after the prototype was evaluated, the Power Company fixed the pole and I put this project on the back burner. The shield gaps shown in the image are a first guess, and the lack of 100% coverage in the shield is just impatience showing through. I just toss this out there as an idea to other loop builders who may wish to explore this area.

I apologize for using direct links here; I am organizing my archives in the hope of creating more permanent refs in the Links section in the future.

10646. Re: Shielded Resonant HF Loop

From: compufriend3@...
Topic: 10645 Message: 10646

HI,

I just scanned your text here and seen your doing something maybe that can really cut down on your reception.. If you have the loop totally covered all the way around it will conduct and make a big conducting loop around your antenna that will interfere with reception.. So go up to the top side, or really anywhere in the circle, and cut a small gap that is not touching anywhere around it . dividing the circle into a broken circle.. to make like a C shape around the loop. The E field will still be shielded and it cant conduct away your signals now.. The first time I ran in to this was with a lightning radar antenna where I did the same thing and wondered why it was so far down in sensitivity..Then some one clued me in on the shield being non contentious around it that way..It made a heck of a difference on my antenna.

From: jfarley44@...
Topic: 10645 Message: 10647

Hi Gerry;

I agree with your concerns 100%. Maybe it's because of a cruddy image, but care was taken to ensure that shielding gaps were maintained in this kluge. In no place does the shielding foil make a complete turn around the loop windings; there is a 1/2" gap which hopefully is visible there. There is also a gap at the top of the loop so that the shield does not form a shunting turn in parallel with the windings.

I expected to take a major hit on the Q but I was pleasantly surprised to find that the Q was diminished by only about 20% (it dropped from around 250 to around 200 at 6900 kHz). While this does knock down the effective height proportionally, the loop still has plenty of output. Likewise, this Q reduction will degrade the minimum discernible signal somewhat; that point is probably moot since it was intended to be used during times of high ambient noise.

Also interesting is the fact that the tuning range of the shielded loop was translated upwards a bit as compared to the free space loop. I surmise that this is because the loop windings are now running in proximity to a ground plane, and their self-inductance has been knocked down a bit, but I am always open to other theories!

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

10649. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-07-01 11:16:50 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 10649

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

10650. Using AVA5-50 for an Active Loop

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-07-01 12:03:39 UTC
From: w4jbb@...
Topic: 10650 Message: 10650

I posted this in the MagLoop group and realized I may have been asking the wrong group.

If memory serves, there is a scrap piece of AVA5-50 (roughly two coils ~4' in diameter) leaned against the wall of my office. It was just left over from a job and is too short for anything up a tower and too cumbersome for use inside a m/w station.

For some time, I have been toying with the idea of building an active loop antenna for roughly 10 - 80m. I'm not a big contester. When I have time, I compete with myself. Usually, I operate from 40 - 20m. However, I do not believe I am using the full potential of my K3 (I probably never will ;)) in an SO2R setting. I *do* have the second receiver. I'd like to be able to use it more and get what I paid for out of the transceiver.

Of all the plans available, from what do most folks have the best results?

AVA5-50 is the replacement for LDF5-50 so it is 7/8" hardline. This particular piece has the hollow conductor (newer AVA5-50 has a foam-filled conductor that we so unceremoniously found out in the field one day and had the wrong connectors). There may be enough coiled up to build two antennas.

I am open to suggestions.

73,
Joel - W4JBB

10651. Steward cores cross for Dallas Lankford antennas?

Yahoo group: loopantennas (2013 — 2017)

Hi,

I have plans to build some of Dallas Lankford's active loops. I see he uses Steward cores that seem to now be unobtanium.
They are:
35T0501-10H
35T1417-00H

Does anyone have cross reference information to a Micrometals/Amidon part number for these toroids?

35T0501 is back to being stocked by DigiKey, although I see they only have 2 pieces in stock as of this morning. It was dropped for a while and then restored with a minimum buy of 8,000 pieces but it's now available in quantity 1 and up. Also shows the 35T1417 parts as being in stock at DigiKey.

These are 'non stock' items but are shown as being available for purchase in quantity 1 and up.

35T mix has a relative permeability of 5000, so a similar FairRite or EPCOS core should be substitutable.

The 10H indicates the core is burnished and coated with epoxy; the 00 is, as I recall, just burnished, not coated.

Jack

Chris,

Further to my previous mail. The
EPCOS
B64290L0044X038 from Digikey may be worth considering. This core has an AL of 5.1uH Verses 4.5 uH of the 35T0501-10H

Deviating off your subject; some of these cores have high loss at HF, so some caution is required if they are being used in a wideband amplifier. For example amplifiers such as the Norton which require a 1 turn Feedback winding closely coupled to the multi-turn Collector winding to avoid core loss. These loses result in a higher than expected noise figure. Hence, the use of thick wire or the use of a 1 turn insulated copper tape with the other winding wound on top of the tape. The preferred core type would normally be a twin hole to ensure close coupling. The core type in the Norton Patent is a twin hole Siemens core!!

Andrew:

The main advantage I see with a binocular core is extended upper and lower frequency range compared with the Norton amps I build with 35T toroid cores. Noise figure differences as measured at 10 MHz and above with an HP8970A NF meter and RFD2305 (think that's the right model number) noise source do not seem to vary more than the error inherent in NF measurements. Some cursory Y type NF measurements in the medium wave band support that conclusion.

My preference is for binocular cores for that reason and I probably will not do another board run for the toroid based Norton amps I sell when the current stock is exhausted.

NF is far more influenced by idle current and the transistors used in the design. Unfortunately there is no idle current that simultaneously maximizes performance of IP2, IP3 and NF.

10658. A bit OT: new delay line kit

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-07-02 03:44:59 UTC
From: pu3hag.l@gmail.com
Topic: 10658 Message: 10658

Hi,

Chavdar Levkov, LZ1AQ - who runs active-antenna.eu - has included a
2nd kit to his site: delay lines for phases antenna array.

I have one of his loop amplifiers still to build. I admit I have zero knowledge on delay lines and need to research a bit on this topic.

Well, research this:

http://www.n6rk.com/Lumped_LC_Delay_Networks.gif

I published this in 2008 and I see that LZ1AQ's delay lines are virtually identical to the ones I described. Maybe he reinvented this stuff. I have an unpublished PC board design that uses jumpers exactly like the LZ1AQ board. However, I learned the hard way not to try to use a binary series of delays. Unless the delays are exact, there will be gaps in coverage and the delay you happen to need might be unrealizable. Instead, what I do is to use a so-called "Radix 1.5" series with ratios of: 1, 1.5, 2.25, 3.375, etc. instead of 1, 2, 4, 8 etc. This has a substantial overlap and allows for fairly sloppy tolerances. I got this idea from the ADC designers at Agilent who used Radix 1.5 to eliminate missing codes. They said everyone in the ADC community knows about this. Except, the variable delay line is analogous to a DAC instead of an ADC. Some principle though.

Rick

Hello Rick,

I don’t really see a problem with Chavdar’s use of a binary delayline sequence because any small phase error is not likely to affect the array performance. That said; I would prefer the use of a potentiometer with a ADC for controlling the phase rather than using a PC com port.

An alternative simplified design could use for example a 20ns delayline with 10 x 2ns tapes selected with 1 pole 10 way switch then buffered by a high z amp. so as not the load the delayline. Additional delay could relay selected prior to the tapped delay line.

I used this scheme over 30 years ago with loop array and active dipole arrays in an effort to combat Soviet Jamming. To be honest it was a total waste of time; because simple two element arrays lack the required directivity when dealing with a multitude arrival angles at HF.

I designed my own continuously variable phase shifter for my steerable interference canceller, which is in the group files section under the name "Antenna Canceller Prototype 02.pdf".

Hi Rick,
1. I know your publications and have included them into Links section of my article
http://www.lz1aq.signacor.com/docs/phased-array/2-ele_phased_array11.pdf
My mind is full with information of different kind (mostly garbage) and I realy do not know wheather some of my ideas are realy mine :-(Moreover the human brain usually refuse to accept unpleasant facts.

2. I have by my side a military automatic antenna tuner (with relays) which was built with radix 1.8. But I think that this delay line does not need that. The idea is to fix the delay to certain value that corresponds to the available distance in your yard.Moreover, the optimal delay is not critical - see my measurements in the above article. Let say you have available distance of 13 m between elements, then you fix the line to 40 ns delay (+ - 2.5 ns tolerance) and that is all. It works.

Hi Andy,
I agree that there are different ways to do the job. But what I want to emphasize is that I do not want to control the line from the shack – the idea is to fix it when you tune your array and then to forget about it. The serial line control just changes the directions and modes.
You are right that 2-element array is the simplest directional antenna. I can built 4-square or bigger array with active elements but the only problem is that my yard is only with 15 x 16 m size and I believe that there are too many hams with small yards. And I can say that there is quite a difference between 2-element and a single antenna.

10664. Cores for Dallas Lankford antennas

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-07-03 17:15:14 UTC
From: Chris Waldrup
Topic: 10664 Message: 10664
Attachments: 1 described; binary payloads are missing from this source WARC

Hi Everyone,

Sorry to be slow in responding. The circuit is the dual ungrounded active flag on page 7. It calls for the Steward cores.
I checked and Steward seems to be based here in town (Chattanooga area) but they have been unresponsive to requests to purchase small quantities of their cores. The last time I checked, Digi Key didn't stock them.

Chris:

How many 35T0501 cores do you need? I can send a few to you, but I don't have the larger cores on hand.

The version of Dallas's J310/J271 amplifier that I sell (Z10130A) does not use 35T0501 cores.
http://www.cliftonlaboratories.com/z10130a_fet_follower.htm for details.

The larger cores are used as common mode chokes in Dallas's design, and I would try DigiKey's PN 495-3857-ND as a substitute. It's an EPCOS part 34mm diameter, PN B64290L48X830 and should have similar performance to the Steward part.

If you absolutely have to have the Steward parts, and if you have a semi-plausible company name, call Steward's sales number and ask for samples.

From: chris.kucera@...
Topic: 10666 Message: 10666

Hi

I've been lurking around the forum for a while but haven't posted anything until now. I have a Pixel Pro 1a antenna that I think the amplifier has gone bad. I was wondering if anyone here has experience with this antenna that could maybe give me some information on how to test the amp. Pixel customer service won't help me out, they just want to sell me a new antenna. If my amp is truly bad, I will buy a Wellbrook like I should have done years ago. Thanks for the help.

Chris

Chris,

Well, the Wellbrook crowd is alive and well - if not much help. I'll try to offer some assistance. Let's debug it. A detailed inspection - and retightening - of all of the connectors & adapters - including in & out of the pre-amp - might find a 'simple' fix. First - is the power inserter green LED lit when the power switch is 'On'? If not, disconnect the cable to the pre-amp and repeat. If it still doesn't lite, unplug the wall warts coaxial plug from the inserter and measure the plug's output voltage - it should be ~20 VAC (Not DC - the rectifier, filter, and regulator are in the inserter.). If it reads zero, you've found your fault - the wall wart. If the wall wart is good, disconnect the transmission line from the pre-amp at the inserter. If the green LED now comes on with the 'On' switch, the fault is either in the pre-amp or the cable to it. While you are at it, measure the center pin to shell voltage of the inserter's input from the transmission line/pre-amp - it should be ~19.6VDC. Reconnect the transmission line at the inserter and disconnect it at the pre-amp. Measure the cable center wire to shield - it should be the same as back at the inserter - or else the feedline cable is bad. If everything is good thus far - and/or the green LED has worked all along, you need to check signal flow.

Unplug the wall wart AC supply. Tune the radio you use to a local MW station and verify that it works by touching it's antenna connection - note the signal level. Reconnect the cable from the radio to the power inserter - and disconnect the transmission line to the pre-amp at the inserter. Touch the now open female F connector (chassis mount on the inserter) and see if the MW station's signal returns. If there is no signal, the fault is in the receiver to inserter cable/adapter or inserter - determine which by replacing the receiver cable. If you are good to here, reconnect the cable and go to the preamp and disconnect the output lead that goes to the 'shack'. "Touching ' the cable's center wire should cause most of the signal to return - if not, your feedline is likely at fault. If it does, it could be your pre-amp - or loop antenna itself.

My Pro-1a was on my deck during a near miss by an F3-F4 tornado 1/12. The deck was cleared off of furniture, etc, and the loop was 'wound up' (I thought the clamp was tight!) and the eave mount's lag bolts were loosened, too. I tightened the connector's and it was fine (I never put sealant on the outside connections!). They are physically stout. I moved 7/13 to a garden home with an HOA and no outside antennas, so the loop is sitting in a tripod mount in the walkup attic and works better than ever now, and, thunderstorms or not, seems to be always left on. The inserter box runs warm, but that's it - pretty stout electrically, too. This site is quiet, too - underground utilities help!

If Pixel is out of business, that would be sad. I think the loop pre-amp was designed by Clifton Labs, if that helps. Good luck!

John

Pixel is alive and well....
We've undergone a name change to InLogisInc http://inlogisinc.com

I've not heard from the gentleman with the PIXEL LOOP issue
He doesn't reach out - we can't help him

We can offer troubleshooting support - and or sell him replacement components if necessary
(SHIPPING is Expensive however)

I am attaching the troubleshooting / setup tips tricks document I've been working on
it may be of some help to him

He can always reach me at

Jack,

Looks like Pixel has sold-out, so you will have to see if the new owner is going to honor a royalty deal, if not then it looks like you are free to sell your amplifiers and maybe even start offering your own active loop antenna. Hire some young muscular kid to roll loops for you with a HF tubbing roller.

It is hard to believe that the previous owner of Pixel did mot tell you of the pending deal and workout the royalty deal with you and the new owner. That is the kind of people that it best not to deal with. The Pixel Active Loop would not be what it is today without your hard work and design of the the heart of it, the amplifier.

Everett

10674. Wellbrook design change

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-07-10 19:09:54 UTC
From: Andrew Ikin
Topic: 10674 Message: 10674

Hello Group,

Here is a post I put on the Yahoo ALA1530 and Wellbrook Groups last month; less the pricing info. for the retro-fit loop amplifier.

For the past 17 years the ALA1530 and similar 1m diameter aluminium loops have been constructed with an integral amplifier. There are over 6000 units in service. The current failure rate is approximately 20 loops per year, which is reasonable for a total running time of 300 million hours.

A third of these failures are due to miss use. The rest are component related or brakes in the amplifier/connexion due wind load mechanical stress on the loop.

However, when a failure does occur the user has been faced with a purchase of the new loop plus a relatively high shipping cost for overseas customers.

Therefore, as of April 2014 the mechanical design has been improved to afford increased reliability and to facilitate ease of servicing:

The amplifier is now housed in a separate module, thus isolating the electronics from the mechanical stress caused by wind loading on the loop. The amplifier to loop wire terminations use tin plated silicone insulated wire and crimp terminals rated down to −40 Celsius. The module sits on top of the loop box and is secured by stainless steel screws.

The amplifier module can be easily replaced in the event of a failure without the customer having to purchase a new loop antenna plus the associated high shipping costs.

A new retrofit amplifier is now available for pre April 2014 loops and is now on the new Wellbrook website; listed under Components.

The amplifier is available for the following rigid loop antennas:

ALA1530

ALA1530LF

ALA1530S+

ALA1530+

ALA330S

LFL1010

The supplied module will be of the latest design. However, only an ALA1530 module will be supplied for the ALA1530+. This is because the new ALA1530 has a lower noise figure and improved loop/amp. frequency related impedance tracking.

The price is GBP70.00 or USD120.00 at the current exchange rate, plus postage.

This amplifier is easy to fit and replaces a previous design.

Kind regards

Andrew

Hi David

I have been in contact with you for a couple months. I have received all your literature you have sent me but have not had any luck with my antenna. I thought I would ask on this forum to see if anyone else has had a problem and if they could help. I have received a couple of nice emails from members giving me some different things to try for which I am grateful for. I thank all the members that have responded and have offered advice.

Chris

10676. Preselector

Yahoo group: loopantennas (2013 — 2017)

From: hikeofyourlife@...
Topic: 10676 Message: 10676

So many little projects left undone. I did something of a workaround here and it made a big difference

I have a approx 100-foot random wire here in SoCal I use for AM BCB and shortwave. I wanted something to help me with HFDL because my house is underneath power lines and everything is quite noisy. I alligator-clipped the input from the antenna to my 30-inch loop antenna inside, back out from THAT loop (which makes my BCB radio work great with no tuning) to my shortwave receiver (DX-440) and audio from that to PC-HFDL to decode airplane transmissions. Another wire from ground on shortwave radio to ground rod outside.

I'm packing up to move so I won't build a preselector till next month but in lieu of that I also added alligator clips to my 1-meter loop made from fridge tubing and an air cap from an old AM-FM stereo. One clip from random wire to cap, from cap to 1M loop, then from loop to ground. Somewhat of a preselector, I guess, but I've at least doubled my HFDL decodes thanks to much lower S/N ratio. Still missing some transmissions, maybe an amp is next in line. Learning as I go here.

Vince in SoCal soon to be much farther north

Subject: [loopantennas] Preselector

So many little projects left undone. I did something of a workaround here and it made a big difference

I have a approx 100-foot random wire here in SoCal I use for AM BCB and shortwave. I wanted something to help me with HFDL because my house is underneath power lines and everything is quite noisy. I alligator-clipped the input from the antenna to my 30-inch loop antenna inside, back out from THAT loop (which makes my BCB radio work great with no tuning) to my shortwave receiver (DX-440) and audio from that to PC-HFDL to decode airplane transmissions. Another wire from ground on shortwave radio to ground rod outside.

I'm packing up to move so I won't build a preselector till next month but in lieu of that I also added alligator clips to my 1-meter loop made from fridge tubing and an air cap from an old AM-FM stereo. One clip from random wire to cap, from cap to 1M loop, then from loop to ground. Somewhat of a preselector, I guess, but I've at least doubled my HFDL decodes thanks to much lower S/N ratio. Still missing some transmissions, maybe an amp is next in line. Learning as I go here.

Vince in SoCal soon to be much farther north

Well with these recent posts of Pixel and the Wellbrook pushed me to inquiring of the group.
I have my opinion, but wanted to request of those who may have real time personal experience.

With the intention to use for amateur radio HF receiving, especially 80 - 40 & 30 meters may I please ask of those who may have used either of these, any opinions, experiences good or bad?

I see Wellbrook has made what looks like a great update to an already respectable product.

I planned to go with a fixed type shielded loop with a remote adjustable control, but that purchase has been put on a delay...so had me looking & thinking of these two commercial type "broadband" loops, but for the cost of them, I had to try and see what do those who actually made the purchase think.

A city lot here with only 20-30 +/- feet available from transmit antennas, however my TS-590 Kenwood offers a separate receive antenna port and Kenwood says the circuit is turned off when in transmit...Also have the KD9SV DXpedition unit to allow a second layer of front-end protection.

So overload should not be an issue for the most-part. Also the loops preamp/amp is not a big requirement as my TS-590 and the KD9SV both have preamps, although the KD9SV is 160/80 only, but ideally would be great to have option to switch the loops amp out to do some A-B-C preamp/amp testing!

Back to where I started...Your thoughts on either loop? please... Pixel - Wellbrook good? bad? even better yet the long shot that some lucky fellow had opportunity to have used both?

Thank You for any help opinion or experience.

I A/B'ed the Pixel loop against a tuned shielded loop
on 160 meters. The Pixel simply runs out of gain on
1.8 MHz and is not as sensitive as the tuned loop.
You are limited by amplifier noise.
Copy was always better on the tuned loop (many contest
QSO's).

I also A/B'ed a Pixel loop (ground mounted) against
a Yagi on a tower. Of course the Yagi trounced it;
probably an unfair comparison.

Was the first comparison comparing two identical-diameter loops?

I have used both the Pixel and the Wellbrook. I purchased the Pixel to replace my PAR End Feed SW antenna. The PAR antenna was good, and the Pixel performed about the same. I receiving more noise on the Pixel that I thought was acceptable and testing things, moving things, etc. did not improve the signal. I was disappointed with the antenna. I sold the Pixel and purchased a Wellbrook. The Wellbrook is fantastic. I do not have the noise issue I had with the Pixel. I am using the same coax, the antenna is mounted on the same pole, the installation is identical. And the Wellbrook works beyond my expectations. My main receiver is a WinRadio G313. I keep the squelch settings at -110 dBm (about S3). I pick up signals from the noise that I could never had heard before. So, I went from the Pixel to the Wellbrook and have never regretted it.
